INFERENCES ON DISTRIBUTION FUNCTIONS UNDER MEASUREMENT ERROR

KARUN ADUSUMILLI, TAISUKE OTSU, AND YOON-JAE WHANG

Abstract. This paper is concerned with inference on the cumulative distribution function (cdf) \( F_{X^*} \) in the classical measurement error model \( X = X^* + \epsilon \). We consider the case where the density of the measurement error \( \epsilon \) is unknown and estimated by repeated measurements, and show validity of a bootstrap approximation for the distribution of the deviation in the sup-norm between the deconvolution cdf estimator and \( F_{X^*} \). We allow the density of \( \epsilon \) to be ordinary or super smooth. We also provide several theoretical results on the bootstrap and asymptotic Gumbel approximations of the sup-norm deviation for the case where the density of \( \epsilon \) is known. Our approximation results are applicable to various contexts, such as confidence bands for \( F_{X^*} \) and its quantiles, and for performing various cdf-based tests such as goodness-of-fit tests for parametric models of \( X^* \), two sample homogeneity tests, and tests for stochastic dominance. Simulation and real data examples illustrate satisfactory performance of the proposed methods.

1. Introduction

This paper is concerned with inference on the cumulative distribution function (cdf) \( F_{X^*} \) in the classical measurement error model \( X = X^* + \epsilon \). Here, we observe \( X \) instead of \( X^* \), and \( \epsilon \) is a measurement error. There is a rich literature on using density deconvolution for estimating the probability density function (pdf) \( f_{X^*} \) (see, Meister, 2009, for a review). By contrast, the literature on estimation and inference for the cdf \( F_{X^*} \) is relatively thin. Fan (1991) proposed a cdf estimator by integrating the deconvolution density estimator with some truncation. This truncation for the integral is circumvented in Hall and Lahiri (2008) (for the case where the pdf \( f_\epsilon \) of \( \epsilon \) is symmetric) and Dattner, Goldenshluger and Juditsky (2011) (for the case where \( f_\epsilon \) is possibly asymmetric). Hall and Lahiri (2008) studied the \( L_2 \)-risk properties of the cdf estimator. Dattner, Goldenshluger and Juditsky (2011) considered minimax rate optimal estimation of \( F_{X^*} \). Both Hall and Lahiri (2008) and Dattner, Goldenshluger and Juditsky (2011) focused on the risk properties of the estimator \( \hat{F}_{X^*}(t_0) \) at a given \( t_0 \) and assumed known ordinary smooth densities for \( f_\epsilon \). These papers demonstrate that, in contrast to the no measurement error case, the cdf estimator \( \hat{F}_{X^*}(t_0) \) typically converges to \( F_{X^*}(t_0) \) at a nonparametric rate. On the other hand, Söhl and Trabs (2012) established a uniform central limit theorem for linear functionals of the deconvolution estimator that can be applied to derive a Donsker-type theorem, i.e., the weak convergence of \( \sqrt{n}\{\hat{F}_{X^*}(\cdot) - F_{X^*}(\cdot)\} \) to a Gaussian process. Söhl and Trabs (2012) considered the case of known ordinary smooth \( f_\epsilon \), and for the Donsker-type result obtained therein, it is demanded that the Fourier transform \( f_\epsilon^{\text{ft}} \) satisfy \( |f_\epsilon^{\text{ft}}(\cdot)| \leq C|\cdot|^{-\beta} \) for some \( \beta < 1/2 \) and

The authors would like to thank seminar participants at Aarhus, Durham, Queen Mary, Toulouse, UBC, Yale, and Econometric Society European Meeting at Lisbon for helpful comments. The authors also acknowledge helpful comments from an associate editor and anonymous referees. Financial support from the ERC Consolidator Grant (SNI 615882) is gratefully acknowledged (Otsu).
The latter excludes the Laplace distribution, for instance. It must be emphasized that (except for Fan, 1991, on the truncated estimator) all these papers concentrate on the case of ordinary smooth and known \( f_\epsilon \), so the cases of super smooth and/or unknown \( f_\epsilon \) (with repeated measurements) are not covered.

In this paper, we investigate validity of asymptotic and bootstrap approximations for the distribution of the maximal deviations

\[ S_n = \sup_{t \in \mathcal{T}} |\hat{F}_{X^*}(t) - F_{X^*}(t)| \] and

\[ T_n = \sup_{t \in \mathcal{T}} |\hat{F}_{X^*}(t) - F_{X^*}(t)| \]

in the sup-norm over some set \( \mathcal{T} \), where \( \hat{F}_{X^*} \) is the deconvolution cdf estimator by Hall and Lahiri (2008) for the case of known \( f_\epsilon \), and \( \hat{F}_{X^*} \) is its adaptation to the case of unknown \( f_\epsilon \) estimated by repeated measurements. Our analysis allows \( f_\epsilon \) to be ordinary or super smooth, or to be unknown and estimated by repeated measurements.

More specifically, our main contributions are described as follows: First, we propose a bootstrap method to approximate the distribution of \( T_n \) and establish its asymptotic validity. This is not a trivial extension from the existing results. Compared to Hall and Lahiri (2008) and Dattner, Goldenshluger and Juditsky (2011), which studied pointwise estimation on \( F_{X^*} \), we investigate uniform inference problems. Even for the same estimator, theoretical developments to analyze the pointwise and uniform properties of nonparametric estimators are very different (see, e.g., Giné and Nickl, 2016, for a general discussion on uniform inference). Furthermore, while these papers (and Söhl and Trabs (2012) mentioned above) focus on the case of known and ordinary smooth \( f_\epsilon \), our analysis also covers the case of unknown and/or super smooth \( f_\epsilon \).

As is known in the literature, the analysis on the super smooth case is very different from the ordinary smooth case. Indeed, to the best of our knowledge, the limiting distributions of \( S_n \) and \( T_n \) for super smooth \( f_\epsilon \) are still open questions. In this paper, we argue that by applying a novel idea in Chernozhukov, Chetverikov and Kato (2014) for constructing bootstrap-based confidence bands to our measurement error setup, we can establish the asymptotic validity of our bootstrap approximation for the distribution of \( T_n \) without deriving its limiting distribution.

Second, for the case of known \( f_\epsilon \), we characterize the convergence rate of the bootstrap approximation error and find that it is of polynomial order under ordinary smooth errors, and logarithmic order under super smooth errors. Furthermore, for the case of known ordinary smooth \( f_\epsilon \), we show that after suitable normalization, the asymptotic distribution of \( S_n \) is characterized by the Gumbel distribution. Although the assumption of known \( f_\epsilon \) is less realistic in empirical economic analyses, these results provide building blocks to establish our main results for the case of unknown \( f_\epsilon \), and are also new in the literature of nonparametric deconvolution methods. In the context of density deconvolution, Bissantz, Dümbgen, Holzmann and Munk (2007) extended Bickel and Rosenblatt’s (1973) construction of uniform confidence bands for densities to the classical measurement error model with the ordinary smooth \( f_\epsilon \). A recent paper by Kato and Sasaki (2016) considered confidence bands of the pdf \( f_{X^*} \) with unknown \( f_\epsilon \). In contrast to these papers, we are concerned with inference on the cdf \( F_{X^*} \).

In the context of nonparametric errors-in-variables regression analysis, Delaigle, Hall and Jamshidi (2015) proposed a bootstrap-based pointwise confidence interval of the regression function for the case of known \( f_\epsilon \). A recent paper by Kato and Sasaki (2017) developed a bootstrap-based uniform confidence band for the case of unknown \( f_\epsilon \). Also in the context of nonparametric inverse regression analysis, which also employs deconvolution methods,
Third, our approximation results on the distributions of $T_n$ and $S_n$ are applicable to various contexts, such as confidence bands for $F_{X^*}$ and its quantiles, and for performing various cdf-based tests such as goodness-of-fit tests for parametric models of $F_{X^*}$, two sample homogeneity tests, and tests for stochastic dominance. We emphasize that some inference problems, such as testing for stochastic dominance, are cumbersome to be handled by density-based methods. Also, even in cases where density-based methods are applicable (e.g., goodness-of-fit testing), the cdf-based methods are expected to have more desirable power properties. All these applications are new in the literature. For example, to the best of our knowledge, our stochastic dominance test is the first test in the literature to be robust to the presence of measurement errors. Dattner, Reiß and Trabs (2016) proposed a quantile estimator of $X^*$ and obtained its uniform convergence rate. This paper provides a confidence band for the quantile function of $X^*$.

This paper is organized as follows. In Section 2, we introduce our setup (Section 2.1) and present the main result, bootstrap approximation for the distribution of $T_n$ in the case of unknown $f_\epsilon$ (Section 2.2). Section 3 presents additional theoretical results on the asymptotic properties of $S_n$ in the case of known $f_\epsilon$. Section 4 contains four applications of the main results: a confidence band for quantiles (Section 4.1), goodness-of-fit test for parametric models of $F_{X^*}$ (Section 4.2), homogeneity test for two samples (Section 4.3), and test for stochastic dominance (Section 4.4). Section 5 presents some simulation evidence. In Section 6, we consider a real data example. In particular, we employ the new test of stochastic dominance to study welfare changes of different population sub-groups using potentially mis-measured income data from Korea. All proofs are contained in the appendix.

2. MAIN RESULT

2.1. Setup and estimator. We first introduce our basic setup. Suppose we observe a random sample $\{X_i\}_{i=1}^n$ generated from

$$X = X^* + \epsilon,$$

(1)

where $X^*$ is an unobservable variable of interest and $\epsilon$ is its measurement error. Throughout the paper, $\epsilon$ is assumed to be independent of $X^*$ (i.e., $\epsilon$ is the classical measurement error). Let $i = \sqrt{-1}$ and $f^\text{th}$ be the Fourier transform of a function $f$. If the pdf $f_\epsilon$ of $\epsilon$ is known, the pdf $f_{X^*}$ of $X^*$ can be estimated by the so-called deconvolution kernel density estimator (see, e.g., Stefanski and Carroll, 1990)

$$\hat{f}_{X^*}(t) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{t - X_i}{h}\right), \quad \text{where } K(u) = \frac{1}{2\pi} \int_{-1}^1 e^{-iu\omega} K^\text{th}(\omega/h) d\omega,$$

(2)

where $h$ is a bandwidth and $K$ is a kernel function with $K^\text{th}$ supported on $[-1, 1]$. Furthermore, if $f_\epsilon$ is symmetric, integration of $\hat{f}_{X^*}$ yields the following estimator for the cdf $F_{X^*}$ of $X^*$ (see, Hall and Lahiri, 2008)

$$\hat{F}_{X^*}(t) = \frac{1}{2} + \frac{1}{n} \sum_{i=1}^n L\left(\frac{t - X_i}{h}\right), \quad \text{where } L(u) = \frac{1}{2\pi} \int_{-1}^1 \frac{\sin(\omega u)}{\omega} K^\text{th}(\omega/h) d\omega.$$

(3)

Birke, Bissantz and Holzmann (2010) and Proksh, Bissantz and Dette (2015) proposed confidence bands for the regression function. We refer Kato and Sasaki (2017) for an extensive survey on this literature.
For the general case of possibly asymmetric \( f_\epsilon \), an estimator for \( F_{X^*} \) is obtained by replacing 
\[ \mathbb{L}(u) \text{ with } \mathbb{L}_n(u) = \frac{1}{\sqrt{n}} \int_{-1}^{1} \text{Im} \left[ e^{-i\omega u} \frac{K^{n}(\omega)}{f^{n}(\omega/h)} \right] d\omega \] 
(Dattner, Goldenshluger and Juditsky, 2011), where \( \text{Im}[\cdot] \) stands for the imaginary part.

The above estimator \( \hat{F}_{X^*} \) requires knowledge of the distribution of \( \epsilon \), which is unrealistic in many applications. In general, however, \( f_\epsilon \) cannot be identified by a single measurement. Identification of \( f_\epsilon \) can be restored if we have two or more independent noisy measurements of the variable \( X^* \). More specifically, suppose that we observe

\[ X_{i,j} = X_i^* + \epsilon_{i,j} \quad \text{for } j = 1, \ldots, N_i \text{ and } i = 1, \ldots, n, \]  
(4)

where \( X_i^* \) is the error-free variable and \( \epsilon_{i,j} \)'s are independently distributed measurement errors from the density \( f_\epsilon \). We thus have \( N_i \) repeated measurements of each variable \( X_i^* \). We shall assume that the number of repeated observations is bounded above (i.e., \( N_i \leq C < \infty \) for all \( i \)).

This assumption is not critical for our theory but allows us to simplify the proofs considerably. Since in practice the number of repeated measurements is small anyway, we do not pursue the generalization to growing \( C \). Under the assumption that \( f_\epsilon \) is symmetric, its Fourier transform \( f_\epsilon^{\text{th}} \) can be estimated by (Delaigle, Hall and Meister, 2008)

\[ \hat{f}_{\epsilon}^{\text{th}}(\omega) = \frac{1}{N} \sum_{i=1}^{n} \sum_{(j_1,j_2) \in J_i} N_i \cos(\omega(X_{i,j_1} - X_{i,j_2}))^{1/2}, \]
(5)

where \( N = \frac{1}{2} \sum_{i=1}^{n} N_i(N_i - 1), J_i \) is the set of \( \frac{1}{2} N_i(N_i - 1) \) distinct pairs \( (j_1, j_2) \) with \( 1 \leq j_1 < j_2 \leq N_i \), and we ignore all the observations with \( N_i = 1 \). By plugging this estimator into (3), we can estimate the cdf \( F_{X^*} \) by

\[ \hat{F}_{X^*}(t) = \frac{1}{2} + \frac{1}{N} \sum_{i=1}^{n} \sum_{j=1}^{N_i} \tilde{L} \left( \frac{t - X_{i,j}}{h} \right) \],

where \( \tilde{L}(u) = \frac{1}{2\pi} \int_{-1}^{1} \frac{\sin(\omega u)}{\omega} \frac{K^{\text{th}}(\omega)}{f^{\text{th}}(\omega/h)} d\omega. \)

(6)

In this section, we are concerned with approximation for the distribution of the maximal deviation

\[ T_n = \sup_{t \in \mathcal{T}} |\hat{F}_{X^*}(t) - F_{X^*}(t)|, \]
(7)

under the sup-norm, where \( \mathcal{T} \) is a compact interval specified by the researcher. A direct use of such approximation is construction of the confidence band for \( F_{X^*} \) over \( \mathcal{T} \). Several other ways to use this approximation are presented in Section 4.

2.2. Bootstrap approximation. In this section, we consider a bootstrap approximation for the distribution of \( T_n \). To construct the bootstrap counterpart of \( T_n \), we suggest resampling from the set of observed variables \( \{X_{i,j}\} \) while keeping the estimated measurement error density \( \hat{f}_{\epsilon}^{\text{th}} \) the same. More precisely, the bootstrap version of \( \hat{F}_{X^*} \) is given by

\[ \hat{F}_{X^*}^{\#}(t) = \frac{1}{2} + \frac{1}{N} \sum_{i=1}^{n} \sum_{j=1}^{N_i} \tilde{L} \left( \frac{t - X_{i,j}^{\#}}{h} \right), \]
(8)

where \( X_{i,j}^{\#} \) is randomly drawn from the pooled observations \( \{X_{i,j}\} \) with equal weights. Then the bootstrap counterpart of \( T_n \) is obtained as \( T_n^{\#} = \sup_{t \in \mathcal{T}} |\hat{F}_{X^*}^{\#}(t) - \hat{F}_{X^*}(t)|. \)
To establish validity of the bootstrap approximation, we impose the following assumptions.

**Assumption C.** (i) \( \{X_{i,j}\}_{i=1}^{N_n} \) is an i.i.d. sample from \( X_{i,j} = X_i^* + \epsilon_{i,j} \) for \( j = 1, \ldots, N_i \), where \( N_1 \leq C < \infty \) for all \( i \). \( X_i^* \) and \( \epsilon_{i,j} \) are independent for all \( i \) and \( j \). (ii) The densities \( f_X, f_{X^*}, \) and \( f_\epsilon \) are bounded and continuous on \( \mathbb{R} \), and \( \inf_{t \in T^\delta} f_X(t) > c \) for some \( c > 0 \) and \( \delta \)-expansion \( T^\delta \) of \( T \). Also, \( E|X^*| < \infty \) and \( E|\epsilon| < \infty \). (iii) \( \sup_{\omega \in \mathbb{R}} \{ (1 + |\omega|)^\gamma |f^{\text{th}}_{X^*}(\omega)| \} < C \) for some \( \gamma, C > 0 \). (iv) \( f^{\text{th}}_\epsilon(\omega) \neq 0 \) for all \( \omega \in \mathbb{R} \), \( f^{\text{th}}_\epsilon(\omega) \) is differentiable at all \( \omega \in \mathbb{R} \), and \( f_\epsilon \) is an even function. (v) There exist \( \epsilon \in (0, 1) \) and \( C > 0 \) such that \( P\{|\epsilon| \geq M\} \leq C (\log M)^{-1/c} \) for all \( M > 0 \).

Assumption C (i) is on the setup wherein we assume that \( \epsilon \) is a classical measurement error.\(^2\) Assumption C (ii) is mild but excludes the Cauchy measurement error. This assumption is required for characterizing the bias of the estimator (see, e.g., Hall and Lahiri, 2008). The Cauchy measurement error is also ruled out in van Es and Uh (2005) who show pointwise asymptotic normality of the deconvolution density estimator. Assumption C (iii), analogous to the so-called Sobolev condition, is also used to characterize the rate for the bias term. Assumption C (iv) contains conditions on \( f_\epsilon \). The first condition is common in the density deconvolution literature but may be relaxed by taking a ridge approach as in Hall and Meister (2007). The last condition is used not only to derive the cdf estimator in (3) as in Hall and Lahiri (2008) but also to obtain the estimator of \( \hat{f}^{\text{th}}_\epsilon \) in (5). Assumption C (v) is an additional regularity condition on the tail behavior of \( \epsilon \). If \( f_\epsilon \) is known, this assumption can be dropped.

We now present two classes of assumptions on the tail behavior of \( f_\epsilon \). The first class of measurement error densities, called the ordinary smooth densities, are presented as follows.

**Assumption OS.** (i) There exist \( \beta > 1/2 \) and \( c, C, \omega_0 > 0 \) such that

\[
|\omega|^{-\beta} \leq f^{\text{th}}_\epsilon(\omega) \leq C|\omega|^{-\beta},
\]

for all \( |\omega| \geq \omega_0 \). (ii) \( K \) is an even function with \( K^{\text{th}}(\omega) = (1 - \omega^q)^r I\{ |\omega| \leq 1 \} \) for some \( q, r \geq 2 \). There exist \( c_1, C_1 > 0 \) such that

\[
n^{-1/4}h^{\beta-1/2} \int |K(u)| du < C_1 n^{-c_1}, \tag{9}
\]

for all \( n \) large enough. Also, letting \( \tilde{K}(u) = \frac{1}{n} \int_0^n \cos(\omega u) \frac{K^{\text{th}}(\omega)}{f^{\text{th}}_\epsilon(\omega/\delta)} \{ |\omega| \geq \omega_0 \} d\omega \), it holds that

\[
h^{\beta-1/2} \int |\tilde{K}(u) - \tilde{K}(u)| du = O(h^s), \tag{10}
\]

for some \( s > 0 \). (iii) As \( n \to \infty \), it holds \( h \to 0, \sqrt{n}h^{\beta-1/2} \to \infty, n^\nu h \to 0 \) for some \( \nu \in (0, 1/2) \), and \( n^{1+2\nu}h^{2(\beta+\gamma)-1} \to 0 \) for some \( \gamma > 0 \). (iv) As \( n \to \infty \), it holds \( \log n/(nh^{4\beta}) \to 0 \) and \( nh^{4\beta+1} \to \infty \). Also, \( \gamma > \beta + 1 \).

\(^2\) The independence assumption between \( X_i^* \) and \( \epsilon_{i,j} \) is standard but can be relaxed to the sub-independence assumption (see, Schennach, 2013). In the context of errors-in-variables regression analysis with repeated measurements, Schennach (2004) and Hu and Sasaki (2015) relaxed the independence assumption for the second and subsequent measurement errors \( \epsilon_{i,j} \) with \( j \geq 2 \). Although it is beyond the scope of this paper, it is interesting to see whether analogous results can be established in our setup.
Assumption OS (i) is a standard condition to characterize ordinary smooth densities. Note that we focus on the case of $\beta > 1/2$, where the cdf estimator $\hat{F}_x$ converges at a nonparametric rate (Dattner, Goldenshluger and Juditsky, 2011). For example, the Laplace distribution corresponds to the case of $\beta = 2$. Also it is known that if $\beta > 1/2$, then $f_\epsilon$ is bounded and continuous. For the case of $\beta < 1/2$, the estimator $\hat{F}_x$ typically converges at the $\sqrt{n}$-rate and a Donsker-type theorem applies (Söhl and Trabs, 2012). Assumption OS (ii) contains conditions for the kernel function. The first condition specifies a particular form for $K$ that is commonly used in the literature (e.g., Delaigle and Hall, 2006). The second condition ensures that the deconvolution kernel $K$ is $L_1$-integrable. The term $n^{-1/4}$ in (9) is required to ensure that the bootstrap counterpart $T_n^\#$ converges to a Gaussian process at a polynomial rate in $n$ (see, Lemma 2 in the appendix). If $f_\epsilon^{fl}$ is twice differentiable, applying the integration by parts formula twice gives
\[
\mathbb{K}(u) = \frac{1}{\pi^2} \int_0^1 \cos(\omega u) \left\{ \frac{K^{fl}(\omega)}{f^{fl}_\epsilon(\omega/h)} \right\}'' d\omega,
\]
and a sufficient condition for (9) is
\[
n^{-1/4} h^{\beta - 1/2} \sup_{|\omega| \leq 1} \left\{ \left| \frac{K^{fl}(\omega)}{f^{fl}_\epsilon(\omega/h)} \right|'' \right\} = O(n^{-c_1}),
\]
for some $c_1 > 0$. The third condition in Assumption OS (ii) assures that $\mathbb{K}$ is well approximated by its trimmed version $\mathbb{K}$. Since
\[
\int \left| \mathbb{K}(u) - \mathbb{K}(u) \right| du = \frac{1}{\pi} \int_0^{\mathbb{K}(u)} \cos(\omega u) \frac{K^{fl}(\omega)}{f^{fl}_\epsilon(\omega/h)} d\omega du,
\]
applying the integration by parts formula twice again implies that a sufficient condition for (10) is given by
\[
h^{\beta + 1/2} \sup_{|\omega| \leq h_{\nu}^{\text{max}}} \max \left\{ \left| \frac{K^{fl}(\omega)}{f^{fl}_\epsilon(\omega/h)} \right|', \left| \frac{K^{fl}(\omega)}{f^{fl}_\epsilon(\omega/h)} \right|'' \right\} = O(h^s),
\]
for some $s > 0$. Based on the above sufficient conditions, it is possible to show that Assumption OS (ii) is satisfied by a large class of ordinary smooth error distributions including Laplace and its convolutions. Intuitively, these conditions mean that $f_\epsilon^{fl}$ should not oscillate too wildly around its trend implied by the ordinary smooth density.

Assumption OS (iii) contains conditions for the bandwidth $h$. The first condition, $h \to 0$, is a standard requirement for controlling the smoothing bias. The second condition, $\sqrt{n}h^{\beta - 1/2} \to \infty$, is imposed to ensure the variance goes to zero. The third condition, $n^\nu h \to 0$, is a technical condition on the bandwidth to ensure that it is not too large; this is easily satisfied for the undersmoothing bandwidth choice. Finally the last condition, $n^{1+2\xi} h^{2(\beta+\gamma)-1} \to 0$, ensures that the bandwidth is undersmoothed relative to the MSE optimal choice, which is $h \propto n^{1/2(\beta+\gamma)-1}$ (see, Hall and Lahiri, 2008). For example, if $h \propto n^{-a}$, then these conditions are satisfied with $a \in \left( \max \left\{ \frac{1+2\xi}{2\beta-1+2\gamma}, \nu \right\}, \frac{1}{2\beta-1} \right)$, which typically holds true by choosing $\xi$ and $\nu$ small enough.

Finally, Assumption OS (iv) lists additional conditions to deal with the case of unknown $f_\epsilon$. The requirement $\gamma > \beta + 1$ says that $f_\epsilon^{\text{fl}}$ is smoother than $f_\epsilon$ by up to a derivative. As
shown in Lemma 1 in the appendix, this ensures that the error from estimating $f^\#_\epsilon$ is asymptotically negligible. Also, we note that the conditions $nh^{4\beta+1} \to \infty$ (Assumption C (iv)) and $n^{1+2\gamma}h^{2(\beta+\gamma)-1} \to 0$ for some $\xi > 0$ (Assumption OS (iii)) hold simultaneously only if $\gamma > \beta + 1$. Delaigle, Hall and Meister (2008) imposed a similar condition to obtain the MSE optimal estimator of $f_\epsilon^\#$ under repeated measurements. They also showed that when the converse holds (i.e., $\gamma < \beta + 1$), the estimation error of $f^\#_\epsilon$ dominates that of $f_\epsilon^\#$, and the estimator $f^\#_\epsilon$ for $f_\epsilon^\#$ given in (5) is no longer optimal (see, p. 673 of Delaigle, Hall and Meister, 2008). The same comment applies when $f_\epsilon^\#$ is ordinary smooth but $f_\epsilon$ is super smooth. When $f_\epsilon$ is smoother than $f_\epsilon^\#$, one may use the estimator by Li and Vuong (1998) based on Kotlarski’s identity; however, such an analysis is more involved and beyond the scope of this paper.

The second class of measurement error densities, called the super smooth densities, are presented as follows.

**Assumption SS.** (i) There exist $\mu, c, C, \omega_0, \lambda > 0$ and $\lambda_0 \in \mathbb{R}$ such that
\[
|c|\bar{\omega}^\lambda \exp(-|\omega|^\lambda/\mu) \leq |f^\#_\epsilon(\omega)| \leq |c|\bar{\omega}^\lambda \exp(-|\omega|^\lambda/\mu),
\]
for all $|\omega| \geq \omega_0$. (ii) $K$ is an even function with $K^r_\tau(\omega) = (1 - \omega^\theta)\mathbb{I}\{|\omega| \leq 1\}$ for some $q, r \geq 2$. There exist $\mu_1 > 2\mu$ and $c_1, C_1 < \infty$ such that
\[
\frac{1}{\varsigma(h)} \int |K(u)|du < C_1 h^{-c_1} \exp\left(\frac{1}{\mu_1 h^\lambda}\right),
\]
for all $n$ large enough, where
\[
\varsigma(h) = h^\vartheta \exp\left(\frac{1}{\mu h^\lambda}\right)
\]
with $\vartheta = \lambda(r + 1/2) + 1/2$. Also, letting $\bar{K}(u) = \frac{1}{\pi} \int_0^1 \cos(\omega u) K^r(\omega) f^\#(\omega/h) \mathbb{I}\{|\omega| \geq h\omega_0\} d\omega$, it holds that
\[
\frac{1}{\varsigma(h)} \int |K(u) - \bar{K}(u)|du = O(n^{-s}),
\]
for some $s > 0$. (iii) $h = (\frac{\mu}{2} \log n + \mu \delta_1 \log \log n)^{-1/\lambda}$ for some $\delta_1 \in ((\vartheta - \gamma)/\lambda + 1, \vartheta/\lambda)$. (iv) $\vartheta_1 < 2\lambda_0/\lambda$ and $\int |\omega^a f^\#_\epsilon(\omega)/f^\#_\epsilon(\omega)|^2 d\omega < \infty$ for some $a > \vartheta - \lambda_0 + 1$.

Assumption SS (i) a standard condition to characterize super smooth densities. Assumption SS (ii) contains conditions on the kernel function, and similar comments apply as for the ordinary smooth case. The condition $\mu_1 > 2\mu$ is required to guarantee that the bootstrap counterpart $T_n^\#$ converges to a Gaussian process at a polynomial rate in $n$ (see Lemma 5 in the appendix). If $f^\#_\epsilon$ is twice differentiable, a sufficient condition for (11) is
\[
\frac{1}{\varsigma(h)} \sup_{|\omega| \leq 1} \left|\left(\frac{K^r(\omega)}{f^\#_\epsilon(\omega/h)}\right)^{''}\right| = O\left(h^{-a} \exp\left(\frac{1}{\mu_1 h^\lambda}\right)\right),
\]
for some $a > 0$. Also, a sufficient condition for (13) is
\[
\exp\left(-\frac{1}{\mu h^\lambda}\right) \sup_{|\omega| \leq \omega_0} \max \left\{\left|\left(\frac{K^r(\omega)}{f^\#_\epsilon(\omega/h)}\right)^{'}\right|, \left|\left(\frac{K^r(\omega)}{f^\#_\epsilon(\omega/h)}\right)^{''}\right|\right\} = O(n^{-a_1}),
\]
for some $a_1 > 0$. For instance, these conditions are satisfied if
\[ \sup_{|\omega| \leq 1} \max \{ |A'(\omega/h)|, |A''(\omega/h)| \} = O \left( h^{-a_1} \exp \left( \frac{1}{\mu_1 h^\gamma} \right) \right), \tag{14} \]
for some $a_1 > 0$, where $A(\omega) = \exp(-|\omega|^2/\mu)/f^0(\omega)$. Based on (14), we can see that Assumptions SS (ii) is satisfied by a large class of super smooth error distributions including Gaussian and its convolutions. Since the function $A$ inherits the differentiability properties of $f^0_t$, the condition (14) intuitively means that $f^0_t$ should not oscillate too wildly around its trend implied by the super smooth density.

Assumption SS (iii) is on the bandwidth $h$. Compared to the ordinary smooth case, we need stricter conditions on the bandwidth to ensure the bias decays to 0 faster than the variance. Note that the MSE optimal bandwidth choice in this instance is $h \propto (\log n)^{-1/\lambda}$; the additional constants and the $(\log \log n)$ term are needed to ensure undersmoothing. We also note that the condition on $\theta_1$ implicitly demands that $\gamma > \lambda$ to ensure that the interval for $\theta_1$ is non-empty. The lower bound for $\theta_1$ is derived from the condition for undersmoothing (see discussion above Lemma 7 in Appendix B.3), which demands that the bias decay to 0 at a rate faster than $\log n$, i.e., $\sqrt{nh^{-\gamma}} = O(\log n)^{-c}$ for some $c > 1$. Indeed, by the definition of $\zeta(h)$ and the expression of $h$ in Assumption SS (iii), we have $\sqrt{nh^{-\gamma}}(\log n)^c \sim \left( \frac{n}{h} \right)^{\frac{1}{\lambda} - \frac{\gamma}{\lambda}}(\log n)^{\frac{1}{\lambda} + \theta_1 + c}$, which implies the lower bound on $\theta_1$. The upper bound on $\theta_1$ is obtained by the requirement that $\sqrt{n/\zeta(h)} \to 0$ so as to ensure the variance decays to 0.

Finally, Assumption SS (iv) lists additional conditions to deal with the case of unknown $f_t$.

Let $\hat{c}_\alpha$ denote the $(1-\alpha)$-th quantile of the bootstrap statistic $T^\#_n$. Under the above assumptions, asymptotic validity of the bootstrap approximation is established as follows.\(^3\)

**Theorem 1.** Suppose that Assumptions C and either OS or SS hold. Then
\[ P \{ T_n \leq \hat{c}_\alpha \} \geq 1 - \alpha - o(1). \tag{15} \]

**Remark 1.** Based on this theorem, we can construct an asymptotic confidence band for $F_{X^*}$ over $\mathcal{T}$ with level $\alpha$ as $[\hat{F}_{X^*}(t) \pm \hat{c}_\alpha]$ for $t \in \mathcal{T}$. To implement the bootstrap approximation in this theorem, we need to choose the bandwidth $h$. For estimation of the cdf $F_{X^*}(t_0)$ at a given $t_0$, Hall and Lahiri (2008) suggested choosing $h$ to minimize the approximate integrated MSE based on the normal reference distribution on $X^*$. For estimation of the quantile function of $X^*$, Dattner, Reiß and Trabs (2016) developed an adaptive method to choose $h$ based on Lepski’s (1990) method. In Section 5 for simulations, we suggest a bandwidth selection rule based on Bissantz, Dümbgen, Holzmann and Munk (2007). The basic idea is to estimate the ideal bandwidth that minimizes the maximal deviation between $\hat{F}_{X^*}$ and $F_{X^*}$ under the sup-norm by utilizing a series of estimates $\hat{F}_{X^*}$ based on different values of $h$.

\(^3\)Here, we present bootstrap approximation results for the statistic $T_n$ which decays to zero. Alternatively, we could have normalized $T_n$ without affecting any of the conclusions. This is analogous to whether we present the bootstrap approximation for the non-normalized object $\hat{\theta} - \theta$ or the normalized one $\sqrt{n}(\hat{\theta} - \theta)$, where $\theta$ is some parameter and $\hat{\theta}$ its estimator.
Remark 2. Theorem 1 says that the approximation error on the right hand side of (15) is of order $o(1)$. On the other hand, Theorem 2 below for the case of known $f_e$ provides more accurate orders. The main obstacle for obtaining an accurate order of the approximation error in the present setup is that the contrast $\hat{F}_{X^\ast}(t) - \tilde{F}_{X^\ast}(t)$ arising from the estimation of $f_e$ is currently bounded by a stochastic term (see Lemma 1) rather than a deterministic one.

Remark 3. In some applications, a separate independent experiment may give us direct observations from $f_e$ (see, e.g., Efroimovich, 1997, and Neumann, 1997). If we have $m$ independent observations $(\epsilon_1, \ldots, \epsilon_m)$ from $f_e$, the Fourier transform $f_{ft}e$ can be estimated as

$$
\tilde{f}_{ft}(t) = \frac{1}{m} \sum_{i=1}^{m} \exp(i t \epsilon_i).
$$

We may use this estimator to obtain an estimator for $F_{X^\ast}$ by replacing $f_{ft}e$ in (3) with $\tilde{f}_{ft}e$. A bootstrap counterpart can be constructed as in (8) by replacing $\hat{f}_{ft}e$ with $\tilde{f}_{ft}e$. The asymptotic validity of such bootstrap approximation can be established by replacing Assumption OS (iv) with the following one.

Assumption OS. (iv)’ As $n \to \infty$, it holds $m \to \infty$, $\sqrt{(n/m)h^3 - 1/2} \log(1/h) \to 0$ and $\log n / (mh^{4/3}) \to 0$.

For the case of super smooth $f_e$, we can supplement Assumption SS with the following condition on $m$.

Assumption SS. (v) As $n \to \infty$, it holds $m/n \to a$ for some $a \in (0, 1)$.

The formal proof for validity of the resulting bootstrap follows by analogous arguments as in the proof of Theorem 1, and is therefore omitted.

Remark 4. Here we focus on the case where repeated measurements on $X^\ast$ are available and $f_{ft}e$ can be estimated by (5) under the symmetry assumption on $f_e$. If $f_e$ is not necessarily symmetric but repeated measurements are available, then we can employ the estimator by Li and Vuong (1998) or Comte and Kappus (2015) based on Kotlarski’s identity. In our current proof, the main difficulty in using these estimators is to obtain a bound on the sup-norm convergence of $\hat{f}_{ft}e$ as in Lemma 1 in Appendix B. Basically we have to follow similar steps by replacing “$\hat{\xi}$” in the proof of Lemma 1 with the estimator of $(f_{ft}e)^2$ by Li and Vuong (1998) or Comte and Kappus (2015). However, due to more complicated constructions of their estimators, such an extension would be substantially different from the current proof. Thus, we would like to leave this extension for future research. Indeed, Kato and Sasaki (2016) also assumed symmetry on $f_e$ for the density deconvolution estimator. Extensions to the asymmetric $f_e$ remain open not only for the confidence band of the cdf $F_{X^\ast}$ but also for the one of the pdf $f_{X^\ast}$.

3. Case of known measurement error distribution

In this section, we present additional theoretical results on the asymptotic properties of the cdf estimator $\tilde{F}_{X^\ast}$ in (3) for the case of known measurement error distribution. The results in this section are building blocks for our main result in Theorem 1. Also, the results here are new
in the statistics literature on nonparametric deconvolution methods, and are of interest in their own right.

This section is concerned with approximation for the distribution of the maximal deviation

$$S_n = \sup_{t \in \mathcal{T}} |\tilde{F}_{X^*}(t) - F_{X^*}(t)|,$$

under the sup-norm, where $\mathcal{T}$ is a compact interval specified by the researcher.

We first establish asymptotic validity of a bootstrap approximation for $S_n$. Consider a nonparametric bootstrap resample $\{X_{i}^\#\}_{i=1}^{n}$ from $\{X_{i}\}_{i=1}^{n}$ with equal weights. The bootstrap counterpart of $S_n$ is given by $S_n^\# = \sup_{t \in \mathcal{T}} |\tilde{F}_{X^\#}(t) - \tilde{F}_{X^*}(t)|$, where $\tilde{F}_{X^\#}$ is defined as in (3) using $X_i^\#$. Let $\tilde{c}_\alpha$ denote the $(1 - \alpha)$-th quantile of the bootstrap statistic $T_n^\#$. The validity of the bootstrap approximation is established as follows.

**Theorem 2.** Suppose that Assumption C (i)-(iv) holds true. Then

$$P\{S_n \leq \tilde{c}_\alpha\} \geq 1 - \alpha - \delta_n,$$

for some positive sequence $\delta_n = O(n^{-c})$ (under Assumption OS (i)-(iii)) or $\delta_n = O((\log n)^{-c})$ (under Assumption SS (i)-(iii)) with $c > 0$.

**Remark 5.** Based on this theorem, we can construct an asymptotic confidence band for $F_{X^*}$ over $\mathcal{T}$ with level $\alpha$ as $C_n(t) = [\tilde{F}_{X^*}(t) \pm \tilde{c}_\alpha]$ for $t \in \mathcal{T}$, which satisfies

$$P\{F_{X^*}(t) \in C_n(t) \text{ for all } t \in \mathcal{T}\} \geq 1 - \alpha - \delta_n,$$

for $\delta_n = O(n^{-c})$ (under Assumption OS (i)-(iii)) or $\delta_n = O((\log n)^{-c})$ (under Assumption SS (i)-(iii)) with some $c > 0$. The approximation error $\delta_n$ provides bounds on the extent of the discrepancy in size (from a nominal level of $\alpha$) when using the bootstrap critical values. We note that this is distinct from the convergence rate of the cdf estimator $\tilde{F}_{X^*}$. We can see that $\delta_n$ is of polynomial order under Assumption OS (the ordinary smooth case), and of logarithmic order under Assumption SS (the super smooth case). We also note from the proof of the theorem that the slower approximation rate of $\delta_n$ for the super-smooth case is solely due to the estimation bias for $F_{X^*}(t)$; if bias correction were possible, the bootstrap approximation error would be of polynomial order in both cases. This is so even as the variance of the cdf estimator $\tilde{F}_{X^*}$ itself goes to 0 at a logarithmic rate.

3.1. **Asymptotic Gumbel approximation for ordinary smooth case.** For the ordinary smooth case, it is also possible to characterize the asymptotic distribution of the standardized object

$$s_n = \sqrt{nh^{2\beta-1}} \sup_{t \in \mathcal{T}} |f_{X}(t)^{-1/2}\{\tilde{F}_{X^*}(t) - F_{X^*}(t)\}|,$$

using the Gumbel distribution. Note that to obtain $s_n$, we normalize the discrepancy $\tilde{F}_{X^*}(t) - F_{X^*}(t)$ by $f_{X}(t)^{-1/2}$, the density function of the mismeasured data $X$.\(^4\) Such normalization by $f_{X}(t)^{-1/2}$ also appears in the case of the deconvolution density estimator for $f_{X^*}$ over $t \in \mathcal{T}$

\(^4\)The reason for this is that the empirical distribution, which is used to sum up the observations to compute $\tilde{F}_{X^*}$, is based on the cdf $F_X$ of the observed data $X$. 

10
(Bissantz, Dümbgen, Holzmann and Munk, 2007). Under additional assumptions, listed in Assumption G in Appendix C, we can follow similar steps as in Bickel and Rosenblatt (1973) and Bissantz, Dümbgen, Holzmann and Munk (2007) to show the following result.

**Theorem 3.** Suppose that Assumptions C (i)-(iv), OS (i)-(iii), and G hold, and \((nh)^{-1}(\log n)^3 \to 0\) as \(n \to \infty\). Then

\[
P \left\{ \left( -2 \log h \right)^{1/2} \left( B^{-1/2} s_n - b_n \right) \leq c \right\} \to \exp(-2 \exp(-c)),
\]

for all \(c \in \mathbb{R}\), where the constant \(B\) and sequence \(b_n\) are defined in Appendix C (eq. (45)).

See Appendix C for a detailed discussion of Assumption G and for the proof of this theorem.

**Remark 6.** As shown in (19), the limiting behavior of \(s_n\) is characterized by the Gumbel distribution. Also based on this theorem, we can see that the convergence rate of \(\sup_{t \in \mathcal{T}} |\hat{F}_n^*(t) - F_X^*(t)|\) is of order \(n^{-1/2} h^{-\beta+1/2} \sqrt{\log h}^{-1}\). Note that in analogous setups, the convergence rate of \(\sup_{t \in \mathcal{T}} |\hat{f}_n^*(t) - f_X^*(t)|\) for the deconvolution pdf estimator in (2) is of order \(n^{-1/2} h^{-\beta-1/2} \sqrt{\log h}^{-1}\) (see, Theorem 1 in Bissantz, Dümbgen, Holzmann and Munk, 2007, and Corollary 1 in Kato and Sasaki, 2016). Thus, the uniform convergence rate of the cdf estimator is faster than that of the pdf estimator by the factor of \(h\). See Dattner, Goldenshluger and Juditsky (2011) for analogous results on the minimax rate for pointwise estimation problems for a given \(t\).

**Remark 7.** Based on (19), and the conventional kernel density estimator \(\hat{f}_X\) for \(f_X\), we can also obtain an asymptotically valid critical value to conduct inference. For example, the asymptotic confidence band at level \(\alpha\) for \(F_X^*\) is given by

\[
C^G_n(t) = \left[ \hat{F}_n^*(t) \pm \sqrt{\frac{B f_X(t) \log n}{nh^{2\beta-1}}} \left( c^G_{\alpha} \right)^{1/2} \right],
\]

for \(t \in \mathcal{T}\), where \(c^G_{\alpha}\) solves \(\exp(-2 \exp(-c^G_{\alpha})) = \alpha\). However, as discussed in the next remark, the asymptotic Gumbel approximation requires additional assumptions and tends to be less accurate than the bootstrap approximation.

**Remark 8.** Compared to the bootstrap approximation, the asymptotic Gumbel approximation has two drawbacks. First, the Gumbel approximation requires an additional assumption (Assumption G). Second, as indicated by Bissantz, Dümbgen, Holzmann and Munk (2007), the approximation error (i.e., \(\delta_n\) in (17) for the bootstrap approximation) given by (19) is typically a logarithmic rate even under Assumption OS, and therefore tends to be less accurate than the bootstrap approximation in (17). This contrast between the asymptotic Gumbel and bootstrap approximations was first clarified by Chernozhukov, Chetverikov and Kato (2014) for construction of confidence bands on the density with no measurement error. Kato and Sasaki (2016) extended their results for confidence bands on the pdf \(f_X^*\) with unknown \(f\). We obtain analogous results for confidence bands on the cdf \(F_X^*\). We also note that in contrast to Chernozhukov, Chetverikov and Kato (2014) and Kato and Sasaki (2016) who employed Gaussian multiplier bootstrap methods, Theorem 2 shows validity of the conventional nonparametric
bootstrap. Accordingly, the techniques used in the proof of Theorem 2 are quite different: in particular, we employ Komlós, Major and Tusnády’s (1975) coupling along with anti-concentration inequalities for Gaussian processes (Chernozhukov, Chetverikov and Kato, 2015) while the latter employ the Slepian-Stein type coupling for suprema of empirical processes constructed in Chernozhukov, Chetverikov and Kato (2014). Finally, we also obtain deterministic bounds on the approximation error of the bootstrap; to the best of our knowledge this is new in the literature on deconvolution.

Remark 9. We note that the asymptotic Gumbel approximation in (19) is available only for the ordinary smooth case. It remains an open question whether we can establish such an asymptotic approximation for the super smooth case. As discussed in Bissantz, Dümbgen, Holzmann and Munk (2007, p. 486) for density deconvolution, the main difficulty is that the limiting form of the deconvolution kernel (eq. (44) in Appendix C) is not available for the super smooth case. On the other hand, as shown in Theorem 2, we emphasize that the bootstrap approximation is valid even for the super smooth case.

4. Applications

4.1. Confidence band for quantile function. In addition to the confidence band for $F_{X^*}$, the results in the previous sections can be utilized to obtain the confidence band for the quantile function of $X^*$. Hall and Lahiri (2008) proposed estimating the $u$-th quantile $Q(u) = F_{X^*}^{-1}(u)$ by

$$
\tilde{Q}(u) = \sup \{ t : \tilde{F}_{X^*}^m(t) \leq u \},
$$

where $\tilde{F}_{X^*}^m(t) = \sup_{y \leq t} \tilde{F}_{X^*}(y)$ is a monotone version of $\tilde{F}_{X^*}(t)$. To obtain the confidence band for the quantile function $Q(u)$ over some interval $[u_1,u_2]$, we impose the following assumptions.

Assumption Q. (i) $F_{X^*}^{-1}(u)$ exists and is unique for all $u \in [u_1,u_2]$ such that $0 < u_1 < u_2 < 1$. There exists an interval $\mathcal{H}$ satisfying $F_{X^*}^{-1}[u_1 - \varepsilon, u_2 + \varepsilon] \subset \mathcal{H}$ for some $\varepsilon > 0$, inf$_{x \in \mathcal{H}} f_{X^*}(x) > 0$, and $0 < \inf_{x \in \mathcal{H}} f_{X^*}(x) \leq \sup_{x \in \mathcal{H}} f_{X^*}(x) < \infty$. (ii) sup$_{x \in \mathcal{H}} |f_{X^*}(x + \delta) - f_{X^*}(x)| \leq M|\delta|^a$ for all $\delta$ sufficiently small, with $a > 0$ (under Assumption OS) and $a = 1$ (under Assumption SS).

Based on these assumptions, we can obtain the asymptotic confidence bands for the quantile function as follows.

Theorem 4. Suppose that Assumptions C, Q, and either OS or SS hold true. Then,

$$
P \left\{ \tilde{Q}(u) - \frac{c_\alpha}{f_{X^*}(\tilde{Q}(u))} \leq Q(u) \leq \tilde{Q}(u) + \frac{c_\alpha}{f_{X^*}(\tilde{Q}(u))} \text{ for all } u \in [u_1,u_2] \right\} \geq 1 - \alpha - o(1).
$$

Remark 10. For the case of known $f_\epsilon$, Dattner, Reiß and Trabs (2016) obtained the uniform convergence rate of their quantile estimator, say $\bar{Q}(u)$, based on the M-estimation method. In particular, Dattner, Reiß and Trabs (2016, Proposition 2.6) obtained that under an MSE optimal choice of the bandwidth,

$$
\sup_{u \in [u_1,u_2]} |\bar{Q}(u) - Q(u)| = O_p \left( \left( \frac{\log n}{n} \right)^{\frac{\gamma}{2(\beta + \gamma) - 1}} \right),
$$

where $\gamma = \frac{1}{\alpha}$.
Thus, Theorem 4 is complementary in that it provides a confidence band for \( Q(u) \) over \( u \in [u_1, u_2] \). Note that as with the case of the cdf, we require under-smoothing to obtain the asymptotically valid confidence band, which excludes the MSE optimal bandwidth.

4.2. **Goodness-of-fit testing.** Another useful application of our results is goodness-of-fit testing on parametric models for \( F_{X^*} \). Consider a parametric model \( \{G_{X^*}(\cdot, \theta) : \theta \in \Theta\} \) for the distribution of the error-free variable \( X^* \) of interest. For simplicity, suppose the measurement error density \( f_\epsilon \) is known as in Section 3. Our method can be adapted to the case of unknown \( f_\epsilon \). The goodness-of-fit testing problem of our interest is

\[
H_0 : F_{X^*}(t) = G_{X^*}(t, \theta) \text{ over } t \in T \text{ for some } \theta \in \Theta,
\]

against negation of \( H_0 \). Let \( \hat{\theta} \) be some \( \sqrt{n} \)-consistent estimator of the true parameter \( \theta_0 \) under \( H_0 \). A typical example of \( \hat{\theta} \) is the maximum likelihood estimator using the density function \( \int g_{X^*}(t - a, \theta)f_\epsilon(a)da \) on the observable \( X \), where \( g_{X^*} \) is the density of \( G_{X^*} \).

To test \( H_0 \), we can employ the Kolmogorov-type statistic

\[
K_n = \sup_{t \in T} |\hat{F}_{X^*}(t) - G_{X^*}(t, \hat{\theta})|,
\]

and its bootstrap counterpart is given by

\[
K_n^\# = \sup_{t \in T} |\hat{F}_{X^*}^\#(t) - G_{X^*}(t, \hat{\theta}^\#)|,
\]

where \( \hat{F}_{X^*}^\# \) and \( \hat{\theta}^\# \) are computed by the (parametric) bootstrap resample \( \{X_i^\#\}_{i=1}^n \) from \( X^\# = X^* + \epsilon^\# \) with \( X_i^\# \sim G_{X^*}(\cdot, \hat{\theta}) \) and \( \epsilon^\# \sim f_\epsilon \). In contrast to the no measurement error case, the cdf estimator \( \hat{F}_{X^*} \) converges at a slower rate than \( \sqrt{n} \). Therefore, if \( \hat{\theta} \) is \( \sqrt{n} \)-consistent, then the estimation error of \( \hat{\theta} \) is negligible under \( H_0 \), and the validity of the bootstrap critical value follows by a modification of the proof of Theorem 2. The result is summarized in the following corollary. Let \( c^K_\alpha \) be the \((1 - \alpha)\)-th quantile of \( K_n^\# \).

**Corollary 1.** Suppose that Assumption C (i)-(iv) holds true, the null \( H_0 \) is satisfied at \( \theta_0 \), \( \sqrt{n}(\hat{\theta} - \theta_0) = O_p(1) \), and the density of \( G_{X^*}(\cdot, \theta) \) is bounded for all \( \theta \) in a neighborhood of \( \theta_0 \). Then

\[
P\{K_n > c^K_\alpha\} \leq \alpha + \delta_n,
\]

for some positive sequence \( \delta_n = O(n^{-c}) \) (under Assumption OS (i)-(iii)) or \( \delta_n = O((\log n)^{-c}) \) (under Assumption SS (i)-(iii)) with \( c > 0 \).

Consistency of the test can be shown analogously. If \( f_\epsilon \) is unknown but repeated measurements on \( X^* \) are available, an analogous result holds true by replacing \( \hat{F}_{X^*} \) and \( \hat{F}_{X^*}^\# \) with \( \hat{F}_{X^*}^- \) and \( \hat{F}_{X^*}^\#^- \), respectively.

4.3. **Homogeneity test.** Our bootstrap and asymptotic approximation results can be extended to two sample problems. Let \( \{X_i\}_{i=1}^n \) and \( \{Y_i\}_{i=1}^m \) be two independent samples of \( X \) and \( Y \). \( X \) is generated as in (1). Also \( Y \) is generated as

\[
Y = Y^* + \delta,
\]
where \( Y^* \) is the unobservable error-free variable with the distribution function \( F_{Y^*} \) and \( \delta \) is its measurement error. We assume \( \delta \) is independent of \( Y^* \). Suppose we wish to test the homogeneity hypothesis

\[
H_0 : F_{X^*}(t) = F_{Y^*}(t) \quad \text{for all } t \in \mathcal{T},
\]

generating the test statistic in Section 4.3. The test statistic for (20) and its bootstrap counterpart are given by

\[
S_{n,m} = \sup_{t \in \mathcal{T}} |\tilde{F}_{X^*}(t) - \tilde{F}_{Y^*}(t)|,
\]

where \( \tilde{F}_{Y^*} \) is the estimator for \( F_{Y^*} \) as in (3) using the sample \( \{Y_i\}_{i=1}^m \). In this case, the bootstrap counterpart of \( S_{n,m} \) is given by

\[
S^\#_{n,m} = \sup_{t \in \mathcal{T}} \left| \tilde{F}^\#_{X^*}(t) - \tilde{F}^\#_{Y^*}(t) - \left\{ \tilde{F}_{X^*}(t) - \tilde{F}_{Y^*}(t) \right\} \right|,
\]

where \( \tilde{F}^\#_{Y^*} \), obtained for the sample \( \{Y_i\}_{i=1}^m \), is defined in the same manner as \( \tilde{F}^\#_{X^*} \). The \((1 - \alpha)\)-th quantile \( c^\#_{\alpha} \) of \( S^\#_{n,m} \) provides an asymptotically valid critical value as follows.

**Corollary 2.** Suppose that Assumption C (i)-(iv) holds true for both \( X = X^* + \epsilon \) and \( Y = Y^* + \delta \), and that \( n/(n + m) \to \tau \in (0, 1) \) as \( n, m \to \infty \). Then under \( H_0 \),

\[
P\{S_{n,m} > c^\#_{\alpha}\} \leq \alpha + \delta_{n,m},
\]

for some positive sequence \( \delta_{n,m} = O(n^{-c}) \) (under Assumption OS (i)-(iii) for both \( \epsilon \) and \( \delta \)) or \( \delta_{n,m} = O((\log n)^{-c}) \) (under Assumption SS (i)-(iii) for both \( \epsilon \) and \( \delta \)) with \( c > 0 \).

An analogous result is available for the case of unknown \( f_i \) by replacing \( \tilde{F}_{X^*} \) and \( \tilde{F}_{Y^*} \) with their estimated versions. Also, if we wish to test the homogeneity hypothesis \( H_0 \) but \( Y \) has no measurement error (i.e., \( Y = Y^* \)), we can replace \( \tilde{F}_{Y^*} \) with the empirical distribution function of the sample \( \{Y_i\}_{i=1}^m \).

4.4. **Stochastic dominance test.** Another intriguing application of our main results is testing the hypothesis of the (first-order) stochastic dominance

\[
H_0 : F_{X^*}(t) \leq F_{Y^*}(t) \quad \text{for all } t \in \mathcal{T},
\]

against the negation of \( H_0 \). By modifying the Kolmogorov-type test in Section 4.3, the test statistic for (20) and its bootstrap counterpart are given by

\[
D_{n,m} = \sup_{t \in \mathcal{T}} \{\tilde{F}_{X^*}(t) - \tilde{F}_{Y^*}(t)\},
\]

\[
D^\#_{n,m} = \sup_{t \in \mathcal{T}} \left\{ \tilde{F}^\#_{X^*}(t) - \tilde{F}^\#_{Y^*}(t) - \left\{ \tilde{F}_{X^*}(t) - \tilde{F}_{Y^*}(t) \right\} \right\},
\]

where \( \tilde{F}^\#_{X^*} \) and \( \tilde{F}^\#_{Y^*} \) are computed as in (3) using nonparametric bootstrap resamples \( \{X^*_i\}_{i=1}^n \) and \( \{Y^*_i\}_{i=1}^m \) from \( \{X_i\}_{i=1}^n \) and \( \{Y_i\}_{i=1}^m \), respectively.

Let \( c^\#_{\alpha} \) denote the \((1 - \alpha)\)-th quantile of the bootstrap statistic \( D^\#_{n,m} \). The bootstrap validity of our stochastic dominance test is established as follows.

**Theorem 5.** Suppose that Assumption C (i)-(iv) holds true for both \( X = X^* + \epsilon \) and \( Y = Y^* + \delta \), and that \( n/(n + m) \to \tau \in (0, 1) \) as \( n, m \to \infty \).
(i): Under $H_0$,  
\[ P\{D_{n,m} > \hat{\epsilon}_\alpha^D\} \leq \alpha + \varrho_{n,m}, \]
for some positive sequence $\varrho_{n,m} = O(n^{-c})$ (under Assumption OS (i)-(iii) for both $\epsilon$ and $\delta$) or $\varrho_{n,m} = O((\log n)^{-c})$ (under Assumption SS (i)-(iii) for both $\epsilon$ and $\delta$) with $c > 0$.

(ii): Let $P_0$ be the set of probability measures of $(X,Y)$ satisfying $H_0$ (but $f_\delta$ and $f_\epsilon$ are fixed) and

\[
0 < c_X \leq \inf_{t \in T} f_X(t) \leq \sup_{t \in T} f_X(t) \leq C_X < \infty,
\]

\[
0 < c_Y \leq \inf_{t \in T} f_Y(t) \leq \sup_{t \in T} f_Y(t) \leq C_Y < \infty,
\]

\[
\sup_{\omega \in \mathbb{R}} \{(1 + |\omega|)^{\gamma_X} |f_{X*}^\alpha(\omega)|\} \leq M_X < \infty,
\]

\[
\sup_{\omega \in \mathbb{R}} \{(1 + |\omega|)^{\gamma_Y} |f_{Y*}^\alpha(\omega)|\} \leq M_Y < \infty,
\]

for some $c_X, c_Y, \gamma_X, \gamma_Y, C_X, C_Y, M_X, M_Y > 0$ that are independent of $(f_X, f_Y)$. Then

\[
\sup_{P \in P_0} P\{D_{n,m} > \hat{\epsilon}_\alpha^D\} \leq \alpha + \varrho_{n,m},
\]

for some positive sequence $\varrho_{n,m} = O(n^{-c})$ (under Assumption OS (i)-(iii)) or $\varrho_{n,m} = O((\log n)^{-c})$ (under Assumption SS (i)-(iii)) with $c > 0$.

(iii): Under the alternative $H_1$ (i.e., $H_0$ is false) and either Assumption OS (i)-(iii) or SS (i)-(iii),

\[
P\{D_{n,m} > \hat{\epsilon}_\alpha^D\} \to 1.
\]

Remark 11. Based on the proof of Theorem 5 (iii), we can characterize some local power properties. Suppose that both measurement errors are ordinary smooth. For any sequence $M_n \to \infty$, $D_{n,m}$ is consistent (i.e., $P\{D_{n,m} > \hat{\epsilon}_\alpha^D\} \to 1$) against local alternatives of the form

\[
H_{1n} : F_{Y*}(t) > F_{X*}(t) + M_n \gamma_n \text{ for some } t \in T,
\]

where

\[
\gamma_n = n^{-1/2} \max \left\{ h_X^{1/2-\beta_X} \sqrt{\log(1/h_X)}, h_Y^{1/2-\beta_Y} \sqrt{\log(1/h_Y)} \right\},
\]

and $h_X$ and $h_Y$ are (possibly different) bandwidths for the estimators $F_{X*}$ and $F_{Y*}$, respectively. A similar expression is available for $\gamma_n$ in the super smooth case with $h_X^{\beta_X-1/2}$ and $h_Y^{\beta_Y-1/2}$ replaced by $\zeta_X^{-1}(h_X)$ and $\zeta_Y^{-1}(h_Y)$ respectively. Finally in the mixed error case, i.e when one of the errors is ordinary smooth while the other is super-smooth, the value of $\gamma_n$ is determined by the super-smooth error (e.g., $\gamma_n = n^{-1/2} \zeta_X(h_X) \sqrt{\log(1/h_X)}$ if $\epsilon$ is super-smooth).

5. Simulation

In this section, we investigate the finite sample performance of the bootstrap uniform confidence band discussed in Section 3 using simulation experiments.

5.1. Simulation designs. We generate data from the model (1), where the unobserved variable of interest $X^*$ is drawn from the normal distribution $N(0, \sigma_X^2)$ and the measurement error $\epsilon$ is drawn from the Laplace distribution $L(0, \sigma_\epsilon^2)$ or the normal distribution $N(0, \sigma_\epsilon^2)$. We fix
\( \sigma_{X^*} = 1 \) and choose \( \sigma_{e} \) so that the 'signal-to-noise ratio (SNR)' is given by \( \sigma_{X^*}/\sigma_{e} = 1, 2, 3.\)

We use the kernel function \( K \) defined by
\[
K(\omega) = \frac{48 \cos \omega}{\pi \omega^4} \left( 1 - \frac{15}{\omega^2} \right) - \frac{144 \sin \omega}{\pi \omega^5} \left( 2 - \frac{5}{\omega^2} \right),
\]
whose Fourier transformation is given by \( K^{\hat{f}}(\omega) = (1 - \omega^2)^3 \cdot \mathbb{1}_{\{|\omega| \leq 1\}}. \) We consider four different sample sizes \( n = 100, 250, 500, 1000 \) and three different confidence levels \( 1 - \alpha = 0.80, 0.90, 0.95. \) The number of simulation and bootstrap repetitions are 2000 and 1000, respectively. We compute the coverage probabilities of our confidence bands for \( F_{X^*} \) over the interval \([-2\sigma_{X^*}, 2\sigma_{X^*}].\)

5.2. **Bandwidth choice.** We adapt the bandwidth selection method of Bissantz, Dümbgen, Holzmann and Munk (2007, Section 5.2) to the cdf estimation. It aims at estimating the bandwidth \( h_{\text{opt}}, \) which minimizes the \( L_\infty \)-distance between \( \tilde{F}_{X^*} \) and the underlying true cdf \( F_{X^*}. \) First we consider \( J \) different bandwidths: \( h_j = h_0 j/J \) for \( j = 1, 2, \ldots, J, \) where \( h_0 \) is a pilot bandwidth. A pilot bandwidth is an over-smoothing bandwidth obtained by multiplying \( \gamma > 1 \) to the normal reference rule of Hall and Lahiri (2008, Section 4.2). The normal reference rule was originally suggested by Delaigle and Gijbels (2004) to estimate density functions, and was modified by Hall and Lahiri (2008) to the setting of estimating distribution functions. For \( j = 2, \ldots, J, \) define the distances
\[
L_\infty(\tilde{F}_{X^*}, F_{X^*}) = ||\tilde{F}_{X^*} - F_{X^*}||_\infty, \quad d^{|\infty|}_{j-1,j} = ||\tilde{F}_{X^*,-1,j} - \tilde{F}_{X^*,j}||_\infty,
\]
where \( \tilde{F}_{X^*,j} \) denotes the deconvolution estimator (3) with bandwidth \( h = h_j \) and \( ||\cdot||_\infty \) denotes the supremum norm. For over-smoothing bandwidths \( h > h_{\text{opt}}, \) \( L_\infty(\tilde{F}_{X^*}, F_{X^*}) \) changes only moderately with increasing bandwidth, while with undersmoothing bandwidths \( h < h_{\text{opt}} \) the distance suddenly increases with decreasing bandwidth. Based on this observation, Bissantz, Dümbgen, Holzmann and Munk (2007, Section 5.2) suggest to estimate \( h \approx h_{\text{opt}} \) by choosing the largest bandwidth at which \( d^{|\infty|}_{j-1,j} \) is more than \( \tau (\tau > 1) \) times greater than \( d^{|\infty|}_{J-1,J}. \) In our simulations, we choose \( J = 20 \) (number of bandwidths), \( \tau = 3, \) and \( \gamma = 1.5. \) (We find that the simulation results are insensitive to the precise choice of the tuning parameters \( J, \tau, \) and \( \gamma. \))

Figures 1 and 2 illustrate the distances over different bandwidths for 3 different random samples with the measurement error drawn from the Laplace and normal distributions, respectively. A comparison of two plots in the figures indicate that the bandwidth at which \( d^{|\infty|}_{j-1,j} \) changes suddenly (marked by a circle, square, or star) is a good indicator of the bandwidth at which the true distance \( L_\infty \) is about to stagnate. A further investigation of the theoretical properties of the bandwidth selection rule would be interesting, but is beyond the scope of our paper; see also Bissantz, Dümbgen, Holzmann and Munk (2007, p.497).

5.3. **Simulation results.** Table 1 presents the empirical coverage probabilities of our bootstrap confidence bands. As a benchmark, it also reports the coverage probabilities of the bootstrap confidence bands using the true \( X^* \). The simulated probabilities are generally close to the

---

\(^5\)The signal-to-noise ratio can be also defined as the ratio \( \sigma_{X}/\sigma_{e} = \sigma_{X^*}/\sigma_{e} + 1 \). Our definition of SNR follows from Bissantz, Dümbgen, Holzmann and Munk (2007); see also Kato and Sasaki (2016).
Figure 1. $L_\infty$ and $d_{j-1,j}^\infty$ distances under Laplace error

Figure 2. $L_\infty$ and $d_{j-1,j}^\infty$ distances under Normal error

nominal confidence levels. As we expected, the coverage errors tend to be smaller when the sample size is larger or when the SNR is larger.

Figures 3 and 4 depict some typical examples for the true cdf (CDF, $F_X$), deconvolution cdf estimate (ECDF, $\tilde{F}_X$), and uniform confidence bands (CB), when the latent true distribution is standard normal and the measurement errors are drawn from Laplace and normal distributions. They show that the uniform confidence bands perform reasonably well even for small sample size $n = 100$ and the widths of the bands shrink substantially as the sample size increases from $n = 100$ to $n = 500$. They also show that the confidence bands with Laplace error gets narrower than those with Normal error as the sample size gets larger. This is consistent with our asymptotic theory since the convergence rates under Laplace and Normal errors are of polynomial and logarithmic order, respectively.

6. Real data example

6.1. Data description. In this section, we apply the stochastic dominance test to the Korea Household Income and Expenditure Survey data to investigate welfare changes of different population sub-groups between 2006 and 2012. We use the data because the OECD report (2008) shows that, among OECD countries, Korea has the most significant variations in within-age

measurement errors in household-based survey data. The survey reports incomes from various sources and consumption of goods and services for each household. We first compute the real household disposable income by adding all incomes, public pension, social benefits and transfers, minus tax, public pension premium and social security fees, after adjusting for inflation using the 2010 consumer price index. We then obtain the individualized data by adjusting the total household disposable income using the square-root equivalization scale, which is a common practice to approximate individual welfare.

Table 2 shows the descriptive statistics for the data. It shows that average real incomes of individuals in all age group except those over 70 have increased from 2006 to 2012. Standard deviations of all incomes have also slightly increased over the same period. The results are consistent with the finding of OECD (2008). However, unless the income distributions are normal, comparison of only the first two moments is not sufficient to draw a conclusion on the uniform ordering of nonparametric income distributions that does not depend on a specific social welfare function. This motivates the use of a stochastic dominance criterion (see, e.g., Levy, 2016, and Whang, 2018).

#### 6.2. Results

We consider two different null hypotheses for each age group: (i) The 2006 income distribution first-order stochastically dominates that the 2012 income distribution (abbreviated to 06 FSD 12) (ii) The 2012 income distribution first-order stochastically dominates the 2006 income distribution (abbreviated to 12 FSD 06). As a benchmark test, we consider the Barrett and Donald (2003, BD)’s test based on the observed incomes, neglecting the presence of measurement errors. We choose the bandwidth as in our simulation experiments and assume Laplace and normal measurement errors. The variance of measurement errors is determined so that the signal-to-noise ratio (SNR) is 1, 2, or 3.6

Table 3 reports the bootstrap p-values of the tests. The BD test implies that, for age groups 25-45 and 45-65, the 2012 income significantly dominates the 2006 income and, for age group

---

6In practice, the error variance is generally not identified without repeated measurements or extraneous information. However, in the case of the CPS income survey data in the U.S., Bound and Krueger(1991) mentioned that “the error variance represents 27.6% of the total variance in CPS earnings for men and 8.9% for women.” According to their remark, the signal-to-ratios (SNRs) are 0.9 for men and 2.35 for women. Since the SNR for our data might be different from those of the CPS data, the latter SNR values cannot be directly applied to our test. Instead, we opt for reporting the test results using SNRs in a “reasonable” range.

Table 3. Bootstrap P-values from BD and our tests

60+, there appears to be no dominance relationship (i.e. the two distributions cross), while for age group 70+ the 2006 income dominates the 2012 income. Similar results hold when we apply our test assuming Laplace measurement errors with relatively large SNR (=2, 3). However, when the SNR is small (SNR=1), or the error distribution is normal, our test shows that, for age group 60+, there is a significant evidence that the 2012 income dominates the 2006 income. Similarly, for age group 65+, the test results vary across different SNRs. This confirms that the presence of measurement errors in the observed data might lead to different conclusions on the stochastic dominance relationship of the underlying true distributions. Without additional information, it is hard to draw a definite conclusion on the stochastic dominance relationship, but we believe that our results can serve as a pilot study for a more systematic future investigation of the dynamics of the income distributions when they are contaminated with measurement errors.
APPENDIX A. PROOFS OF THEOREMS

Notation: Hereafter, let $P^#$ and $E^#$ be the conditional probability and expectation under the bootstrap distribution given $\{X_i\}_{i=1}^n$, respectively. Also, denote
\[
\mathbb{L}(u) = \frac{1}{\pi} \int_0^1 \frac{\sin(\omega u)}{\omega} \frac{K^f(\omega)}{f^b(\omega/h)} I[|\omega| \geq h\omega_0] d\omega,
\]
\[
G_n(t) = r(h) \int \mathbb{L} \left( \frac{t - a}{h} \right) f_X(a)^{1/2} dW(a),
\]
\[
p_c(G_n) = \sup_x P \left\{ \sup_{t \in T} |G_n(t) - x| \leq \varepsilon \right\},
\]
where $W$ is a (two-sided) Wiener process on $\mathbb{R}$, $f_X$ is the pdf of $X$, and
\[
r(h) = \begin{cases} h^{\beta - \frac{1}{2}} & \text{under Assumption OS} \\ 1/\zeta(h) & \text{under Assumption SS} \end{cases},
\]
with $\zeta(h)$ defined in eq. (12) of the paper. Note that analogous to $\mathbb{K}$ (defined in Assumptions OS (ii) and SS (ii)), $\mathbb{L}$ is considered as a trimmed version of $\mathbb{L}$. Due to the trimming, properties of the Fourier transform guarantee $\mathbb{L} \in L_2(\mathbb{R})$ for each $h$ under the assumption $f^b \neq 0$, and this guarantees existence of the stochastic integral in the definition of $G_n$.

Also, for any $a \in (0, 1)$, let $c_a$ denote the constant such that $\sqrt{nh^{\beta - \frac{1}{2}} c_a}$ is the $(1 - a)$-th quantile of $\sup_{t \in T} |G_n(t)|$.

A.1. Proof of Theorem 1. Since the proof is similar, we only present the proof for the ordinary smooth case. Define
\[
\hat{D}_n^\#(t) = \sqrt{nh^{\beta - 1/2}} \{ \hat{F}_X^\#(t) - \hat{F}_X^\#(t) \}, \quad \hat{D}_n^\#(t) = \sqrt{nh^{\beta - 1/2}} \{ \hat{F}_X^\#(t) - \hat{F}_X^\#(t) \}.
\]
Also, let $f^b_X(\omega) = N^{-1} \sum_{i,j} e^{i\omega X_{i,j}}$ be the bootstrap counterpart of the empirical characteristic function $f^b_X(\omega) = N^{-1} \sum_{i,j} e^{i\omega X_{i,j}}$.

We first show that there exist $c, C > 0$ such that
\[
P^\# \left\{ \sup_{t \in T} |\hat{D}_n^\#(t) - \hat{D}_n^\#(t)| \geq C n^{-c} \right\} = o_p(1). \tag{21}
\]
By Lemma 1, it is enough for (21) to guarantee that there exist $c, C > 0$ satisfying
\[
P^\# \left\{ \sqrt{nh^{\beta - 1/2}} \sup_{t \in T} |\hat{F}_X^\#(t) - \hat{F}_X^\#(t)| \geq C n^{-c} \right\} = o_p(1).
\]
To this end, note that
\[
\hat{F}_X^\#(t) - \hat{F}_X^\#(t) = \frac{1}{2\pi} \int_{-1/h}^{1/h} \text{Im} \left\{ e^{-i\omega t} \left\{ f^b_X(\omega - f^b_X(\omega) \right\} \left\{ \hat{\xi}(\omega) - \xi(\omega) \right\} K^f(h\omega) d\omega \right. \\
+ \frac{1}{2\pi} \int_{-1/h}^{1/h} \text{Im} \left\{ e^{-i\omega t} f^b_X(\omega) \right\} \left\{ \hat{\xi}(\omega) - \xi(\omega) \right\} K^f(h\omega) d\omega \\
= C_{1n}(t) + C_{2n}(t).
\]
The second term $C_{2n}(t)$ equals to $\hat{F}_X(t) - \hat{F}_{X^*}(t)$ whose bound is given in Lemma 1. Thus, we only need to consider the first term $C_{1n}(t)$. By expanding the expectations, it can be shown

\[ E^\# \left[ \int_{\omega_0}^{1/h} \omega^{-a}|\hat{f}_X^\#(\omega) - \hat{f}_X^0(\omega)|^2 d\omega \right] = O_p((nh^{1-a})^{-1}), \]

for all $a < 1$, and analogous arguments as in the proof of Lemma 1 yield $\sup_{t \in T} |C_{1n}(t)| = O_p((nh^{3\beta})^{-1})$ with probability approaching one. Therefore, by paralleling the arguments in the proof of Lemma 1, we obtain (21).

We now proceed by verifying the conditions in the proof of Theorem 2. Lemmas 1 and 2 ensure existence of a sequence $\epsilon_n = O(n^{-c})$ with some $c > 0$ such that

\[ P \left\{ \sup_{t \in T} \sqrt{n}h^{-1/2} \{ \hat{F}_X(t) - F_X(t) \} - G_n(t) \geq \epsilon_n \right\} = o_p(1). \tag{22} \]

Furthermore by Lemma 3, combined with (21), we have that

\[ P^\# \left\{ \sup_{t \in T} \sqrt{n}h^{-1/2} \{ \hat{F}_X^*(t) - \hat{F}_{X^*}(t) \} - \hat{G}_n(t) \geq \epsilon_n \right\} = o_p(1). \tag{23} \]

Therefore, by (22) and (23), the conclusion follows by paralleling the arguments in the proof of Theorem 2.

A.2. Proof of Theorem 2. We only prove the statement under Assumption OS (i.e., the ordinary smooth case). The statement under Assumption SS is shown by a similar argument using Lemmas 5-7.

First, we prove

\[ P \left\{ \sqrt{n}h^{\beta - \frac{1}{2}} \tilde{c}_\alpha > \sqrt{n}h^{\beta - \frac{1}{2}} c_{\alpha + \delta n} - \epsilon_{1n} \right\} \geq 1 - \delta_{2n}, \tag{24} \]

for some $\epsilon_{1n}, \delta_{1n}, \delta_{2n} = O(n^{-c})$ with $c > 0$. Lemma 3 implies that with probability greater than $1 - \delta_{2n}$,

\[ 1 - \alpha = P^\# \left\{ \sqrt{n}h^{\beta - \frac{1}{2}} \sup_{t \in T} |\hat{f}_X^*(t) - \hat{F}_{X^*}(t)| \leq \sqrt{n}h^{\beta - \frac{1}{2}} \tilde{c}_\alpha \right\} \]

\[ \leq P^\# \left\{ \sup_{t \in T} |\tilde{G}_n(t)| \leq \sqrt{n}h^{\beta - \frac{1}{2}} \tilde{c}_\alpha + \epsilon_{1n} \right\} + \delta_{1n}, \]

for some $\epsilon_{1n}, \delta_{1n}, \delta_{2n} = O(n^{-c})$ with $c > 0$, where $\tilde{G}_n$ has the same distribution as $G_n$ under $P^\#$. Since $\sqrt{n}h^{\beta - \frac{1}{2}} \tilde{c}_\alpha$ is also the $(1 - \alpha)$-th quantile of $\sup_{t \in T} |\tilde{G}_n(t)|$ under $P^\#$, the above inequality implies

\[ P^\# \left\{ \sup_{t \in T} |\tilde{G}_n(t)| \leq \sqrt{n}h^{\beta - \frac{1}{2}} \tilde{c}_\alpha + \delta_{1n} \right\} \leq P^\# \left\{ \sup_{t \in T} |\tilde{G}_n(t)| \leq \sqrt{n}h^{\beta - \frac{1}{2}} \tilde{c}_\alpha + \epsilon_{1n} \right\} \]

with probability greater than $1 - \delta_{2n}$. Thus, we obtain (24).

The main result is thus obtained from the following sequence of inequalities
where the first inequality follows from Lemma 2, the second inequality follows from (24), the third inequality follows from the definitions of \( \tilde{\epsilon}_n = \epsilon_{1n} + \epsilon_n \) and \( p_c(G_n) \), along with the fact \( G_n \) and \( \overline{G_n} \) have the same distribution (which ensures \( p_c(|G_n|) \leq 2p_c(G_n) \)), the equality follows from the definition that \( \sqrt{n}h^{\beta - \frac{1}{2}} \tilde{\epsilon}_n+\delta_n \) is the \( (1 - \alpha - \delta_{1n}) \)-th quantile of \( \sup_{t \in T}|G_n(t)| \), and the last inequality follows from Lemma 4. Therefore, letting \( \delta_{3n} = \delta_{1n} + M \epsilon_n \sqrt{\log(1/h)} + \delta_n + \delta_{2n} \), we have

\[
P\{ T_n \leq \tilde{\epsilon}_n \} \geq 1 - \alpha - \delta_{3n}.
\]

Since \( \delta_n, \delta_{1n}, \delta_{2n}, \epsilon_n \) are all positive sequences of order \( O(n^{-a}) \) with some \( a > 0 \) and \( \sqrt{\log(1/h)} \) is a log-rate, we obtain (17).

We only prove the theorem under Assumption OS (i.e., the ordinary smooth case). The proof under Assumption SS follows by a similar argument using Lemmas 5-7.

We make the following preliminary observations. First, by the techniques employed in Lemmas 2-4, we can show\(^7\)

\[
\sup_{t \in H} |\hat{f}_{X^*}(t) - f_{X^*}(t)| = O_p(n^{\gamma}).
\]  

(25)

Next by Dattner, Reiß and Trabs (2016, Proposition 2.1), \( \|\hat{f}_{X^*}\|_1 < \infty \) and \( \int_{-\infty}^{\infty} \hat{f}_{X^*}(t)dt = 1 \) under Assumption C. Thus, we have \( \hat{F}_{X^*}(t) = \int_{-\infty}^{t} \hat{f}_{X^*}(u)du \) or equivalently \( \hat{F}_{X^*}(t) = \hat{f}_{X^*}(t) \). The latter ensures \( \hat{F}_{X^*} \) is continuous.

We now show that\(^8\)

\[
\sup_{u \in [u_1, u_2]} |\hat{Q}(u) - Q(u)| = o_p(n^{-c_1}),
\]  

(26)

for some \( c_1 > 0 \). By Hall and Lahiri (2008, Theorem 3.7), \( \hat{Q}(u) \) converges to \( Q(u) \) for each \( u \in [u_1, u_2] \). Now \( Q_n(u) \) is monotone at each \( n \) by construction while \( Q(u) \) is continuous by Assumption Q (i). Hence we can modify the proof of the Glivenko-Cantelli theorem (see, Billingsley, 1995, p. 233), to strengthen the pointwise consistency to a uniform one, i.e.,

\[
\sup_{u \in [u_1, u_2]} |\hat{Q}(u) - Q(u)| = o_p(1),
\]  

(27)

\(^7\)An analogous result applies for the super smooth case by Lemmas 5-7 with the rate replaced by \( O_p((\log n)^{-\gamma}) \) for some \( c > 1 \) under the assumption \( \gamma > \lambda \) and an MSE optimal bandwidth choice.

\(^8\)For the super smooth case, we can employ similar arguments to show that \( \sup_{u \in [u_1, u_2]} |\hat{Q}(u) - Q(u)| = o_p((\log n)^{-c_1}) \) for some \( c_1 > 1 \).
(see also, Bassett and Koenker, 1986, Theorem 3.1). As $\hat{F}_X^\ast(Q(u)) = u$ for all $0 < u < 1$. Consequently,

$$\hat{F}_X^\ast(Q(u)) = F_X^\ast(Q(u)) = F_X^\ast(Q(u)) - f_X^\ast(Q(u))(\hat{Q}(u) - Q(u)),$$

for some $\hat{Q}(u)$ such that $|\hat{Q}(u) - Q(u)| \leq |\hat{Q}(u) - Q(u)|$, and we obtain

$$\sup_{u \in [u_1, u_2]} |\hat{Q}(u) - Q(u)| \leq \left( \inf_{u \in [u_1, u_2]} |f_X^\ast(Q(u))| \right)^{-1} \sup_{u \in [u_1, u_2]} |\hat{F}_X^\ast(Q(u)) - F_X^\ast(Q(u))|$$

By (27) and Assumption Q (i) ($\inf_{x \in \mathcal{H}} f_X^\ast(x) > 0$), we can verify $\inf_{u \in [u_1, u_2]} |f_X^\ast(Q(u))| > 0$ with probability approaching one. Furthermore, we have

$$\sup_{u \in [u_1, u_2]} |\hat{F}_X^\ast(Q(u)) - F_X^\ast(Q(u))| \leq n^{-1/2} h^{-\frac{1}{2}} \sup_{t \in \mathcal{H}} |\mathcal{G}_n(t)| + o_p(1) = O_p\left(\left(\frac{\log(1/h)}{nh^{2\beta-1}}\right)^{1/2}\right),$$

where the inequality follows from Lemma 2 after employing the fact $\{Q(u) : u \in [u_1, u_2]\} \subset \mathcal{H}$ with probability approaching one due to Assumption Q (i) and (27). The equality follows from $E[\sup_{t \in \mathcal{H}} |\mathcal{G}_n(t)|] = O(\sqrt{\log(1/h)})$ (by the proof of Lemma 4). Combining these results, we obtain (26) under Assumptions OS (iii) and B (ii).

We now proceed to the main part of the proof. Noting that $\hat{Q}(u) - Q(u) = f_X^\ast(Q(u))^{-1}\{\hat{F}_X^\ast(Q(u)) - F_X^\ast(Q(u))\}$, we have

$$P\left\{ \hat{Q}(u) - Q(u) \leq \frac{\tilde{c}_\alpha}{f_X^\ast(Q(u))} \leq Q(u) \leq \hat{Q}(u) + \frac{\tilde{c}_\alpha}{f_X^\ast(Q(u))} \right\} = P\left\{ \sup_{u \in [u_1, u_2]} |\hat{F}_X^\ast(t) - F_X^\ast(t)| \leq \tilde{c}_\alpha(1 - \Delta_n) \right\} - o(1),$$

where $\Delta_n = \sup_{u \in [u_1, u_2]} |\hat{F}_X^\ast(Q(u)) - f_X^\ast(Q(u))| f_X^\ast(Q(u))|$ and the inequality follows from the fact

$$P\left\{ \{Q(u) : u \in [u_1, u_2]\} \subset \mathcal{H} \right\} \rightarrow 1 \text{ by Assumption Q (i) and (26).}$$

Also note that $\Delta_n = O_p(n^{-\epsilon})$ by Assumption Q (i)–(ii), (25), and (26). We now have the following sequence of inequalities

$$P\left\{ \sup_{t \in \mathcal{H}} |\mathcal{G}_n(t)| \leq \sqrt{nh^{\beta - 1/2} c_{\alpha + \delta_1 n}} - \epsilon_n \right\} \leq P\left\{ \sup_{t \in \mathcal{H}} |\mathcal{G}_n(t)| \leq \frac{\sqrt{nh^{\beta - 1/2} c_{\alpha + \delta_1 n}} - \epsilon_n}{1 - \Delta_n} - \delta_n - \delta_2 n \right\}$$

and

$$P\left\{ \sup_{t \in \mathcal{H}} |\mathcal{G}_n(t)| \leq 2p_{c_n}(\mathcal{G}_n) - \delta_n - \delta_2 n \geq 1 - \alpha - \delta_1 n - \delta_n - \delta_2 n - 2p_{c_n}(\mathcal{G}_n), \right\}$$

where the first inequality follows from Lemma 2, the second inequality can be derived by Lemma 3 and a similar argument in the proof of Theorem 1, the third inequality follows from the definitions of $c_n = c_n + \epsilon_n (1 - \Delta_n) + \sqrt{nh^{\beta - 1/2} c_{\alpha + \delta_1 n}} \Delta_n$ and the concentration function. Note that Lemma 4 implies $p_{c_n}(\mathcal{G}_n) \leq C \epsilon_n \sqrt{\log n}$. Recalling that $\sqrt{nh^{\beta - 1/2} c_{\alpha + \delta_1 n}}$ is the $(\alpha + \delta_1 n)$-th quantile of $\sup_{t \in \mathcal{H}} |\mathcal{G}_n(t)|$, by Chernozhukov, Chetverikov and Kato (2014, Lemma B1),

$$\sqrt{nh^{\beta - 1/2} c_{\alpha + \delta_1 n}} \leq E\left[ \sup_{t \in \mathcal{H}} |\mathcal{G}_n(t)| \right] + \sqrt{2 \log(\alpha + \delta_1 n)}.$$
Since $E[\sup_{t \in T} |\mathcal{G}_n(t)|] = O(\sqrt{\log(1/h)})$, this implies $\sqrt{nh^{3/2}c_{n+1}} = O(\sqrt{\log n})$ under Assumptions OS (iii) and B (ii). By the above and the rates of $\epsilon_n, \epsilon_{1n}$, it follows $p_{\epsilon_n}(G_n) = O_p(n^{-c_2})$ for some $c_2 > 0$. Furthermore, by Lemmas 2 and 3, $\delta_n, \delta_{1n}$, and $\delta_{2n}$ are also $O(n^{-c_3})$ for some $c_3 > 0$. Combining these results, the conclusion follows.

A.4. Proof of Theorem 5. We shall assume for simplicity that $f_\epsilon = f_\delta$, and consequently that the bandwidth choices for both estimators are the same. We only prove for the case of ordinary smooth error density as the proof for super-smooth density follows by the same arguments.

Assume that that the smoothness parameter in the former case is $\beta$. Let

$$
\mathcal{G}^D_{n,m}(t) = h^{\beta-1/2} \left\{ \int \bar{L} \left( \frac{t-a}{h} \right) f_X(a) 1/2 dW_1(a) - \sqrt{\frac{n}{m}} \int \bar{L} \left( \frac{t-a}{h} \right) f_Y(a) 1/2 dW_2(a) \right\},
$$

where $W_1$ and $W_2$ are two independent (two-sided) Wiener processes on $\mathbb{R}$ (for $f_\epsilon \neq f_\delta$ or unequal bandwidths, the $\bar{L}$ functions in the above integrals would also be different). Also define

$$
\Psi_{n,m}(t) = \{ F_{X*}(t) - F_X(t) \} - \{ F_{Y*}(t) - F_Y(t) \},
$$

$$
\Psi^#_{n,m}(t) = \{ F_{X*}(t) - F_X(t) \} - \{ F_{Y*}(t) - F_Y(t) \}.
$$

A.4.1. Proof of (i). Since the samples $\{X_i\}_{i=1}^n$ and $\{Y_i\}_{i=1}^m$ are independent of each other, by the arguments of Lemma (2)-(4), we can show the following: For some sequences $\epsilon_n, \delta_n = O(n^{-c})$,

$$
P \left\{ \sup_{t \in T} \left| \sqrt{nh^{\beta-1/2} \Psi_{n,m}(t) - \mathcal{G}^D_{n,m}(t)} \right| > \epsilon_n \right\} < \delta_n. \tag{28}
$$

Furthermore with probability greater than $1 - \delta_{2n}, \delta_{2n} = O(n^{-c})$, there exist sequences $\epsilon_{1n}, \delta_{1n} = O(n^{-c})$ such that

$$
P^# \left\{ \sup_{t \in T} \left| \sqrt{nh^{\beta-1/2} \Psi^#_{n,m}(t) - \mathcal{G}^D_{n,m}(t)} \right| > \epsilon_{1n} \right\} < \delta_{1n}, \tag{29}
$$

where $\mathcal{G}^D_{n,m}$ is a tight Gaussian process with the same distribution as $\mathcal{G}^D_{n,m}$ under $P^#$. Finally it also holds that

$$
p_{\epsilon_n}(G_{n,m}) \leq M \epsilon_n \sqrt{\log(1/h)}, \tag{30}
$$

for any sequence $\epsilon_n = O(n^{-c})$ and some $M < \infty$. Now

$$
P \left\{ D_{n,m} \leq \hat{c}_\alpha^D \right\} \geq P \left\{ \sup_{t \in T} \Psi_{n,m}(t) - \sup_{t} \{ F_{X*}(t) - F_{Y*}(t) \} \leq \hat{c}_\alpha^D \right\} \geq P \left\{ \sup_{t \in T} \Psi_{n,m}(t) \leq \hat{c}_\alpha^D \right\},
$$

where the last equality follows from $\sup_{t} \{ F_{X*}(t) - F_{Y*}(t) \} \leq 0$ under $H_0$. Using equations (28)-(30), by paralleling the arguments in the proof of Theorem 1, we can show that

$$
P \left\{ \sup_{t \in T} \Psi_{n,m}(t) \leq \hat{c}_\alpha^D \right\} \geq 1 - \alpha - \varrho_{n,m}.
$$

Hence the claim follows immediately.

A.4.2. Proof of (ii). It is enough to show that $\rho_{n,m}$ does not depend on $P \in \mathcal{P}_0$. To this end, it is enough to show uniform validity of equations (28)-(30). Since these equations are essentially two-sample counterparts of Lemmas (2)-(4), it suffices to check uniform validity of the latter.
Note that for Lemma (2), uniformity of the bias term follows by the argument in Hall and Lahiri (2008, Theorem 3.2) using the uniform version of the Sobolev condition (i.e. the constants $M_X$ and $M_Y$ do not depend of $(F_X\cdot, F_Y\cdot)$). For the stochastic term, the constants appearing in the KMT coupling in the proof of Lemma (2) are universal, and constants and sequences in other parts do not depend on $P \in \mathcal{P}_0$. Thus, $\delta_n$ in Lemma (2) does not depend on $P \in \mathcal{P}_0$. Similarly, uniformity of Lemma (3) is also verified.

For Lemma (4), it is enough to guarantee that $\sigma_n(t)$ is bounded away from zero and above by universal constants that do not depend on $P \in \mathcal{P}_0$. This is guaranteed by the assumption that $f_X$ and $f_Y$ are bounded away from zero and above by universal constants that do not depend on $P \in \mathcal{P}_0$.

**A.4.3. Proof of (iii).** Let $c^D_\alpha$ be a constant such that $\sqrt{n}h^{\beta-1/2}c^D_\alpha$ is the $(1 - a)$-th quantile of $\sup_{t \in \mathcal{T}} \mathcal{G}_{n,m}^{D}(t)$. Using equation (29) and mirroring the arguments in the proof of Theorem 1, we have that

$$P \left\{ \sqrt{n}h^{\beta-1/2}c^D_\alpha < \sqrt{n}h^{\beta-1/2}c^D_{\alpha-\delta_1} + \epsilon_1 \right\} \geq 1 - \delta_{2n}. \tag{31}$$

Under $H_1$, there exists $t^* \in \mathcal{T}$ such that $\mu = F_X(t^*) - F_Y(t^*) > 0$. Then we obtain

$$P \{ D_{n,m} > \hat{c}^D_\alpha \} \geq P \left\{ \sqrt{n}h^{\beta-1/2}D_{n,m} > \sqrt{n}h^{\beta-1/2}c^D_{\alpha-\delta_1} + \epsilon_1 \right\} - \delta_{2n}$$

$$\geq P \left\{ \mathcal{G}_{n,m}^{D}(t^*) > \sqrt{n}h^{\beta-1/2}c^D_{\alpha-\delta_1} - \sqrt{n}h^{\beta-1/2}\frac{1}{2}\mu + \epsilon_1 + \epsilon \right\} - \delta_{2n} - \delta_n,$$

for some $\epsilon_n, \delta_n = O(n^{-c})$ with some $c > 0$, where the first inequality follows from (31) and the second inequality follows from (28). By analogous arguments as in the proof of Theorem 5, we can show $\sqrt{n}h^{\beta-1/2}c^D_{\alpha-\delta_1} = O(\sqrt{\log(1/h)})$. However under Assumption OS (iii), $\sqrt{n}h^{\beta-1/2}\log^{-1/2}(1/h)\mu \to +\infty$; hence the conclusion follows immediately.

**Appendix B. Lemmas**

Hereafter we use the following notation. By the Ito isometry, the variance function of the Gaussian process $\mathcal{G}_n$ can be shown to be

$$\sigma_n(t) = h^2 \int L^2(a) f_X(t - ha)da.$$

Let $\bar{\sigma}_n(0) = \sup_t \sigma_n(t)$ and $\underline{\sigma}_n = \inf_t \sigma_n(t)$. Assumption C (i) $(\inf_{t \in \mathcal{T}} f_X(t) > c > 0)$ guarantees that $\underline{\sigma}_n > 0$ for all $n \in \mathbb{N}$.

Also, define the variance sub-metric $d_n(s, t) = Var(\mathcal{G}_n(s) - \mathcal{G}_n(t))$ on $\mathcal{T}$.

**B.1. Lemma for Theorem 1.**

**Lemma 1.** Suppose that Assumptions C and either OS or SS hold. Then for some $c > 0$,

$$\sqrt{n}h^{\beta-1/2} \sup_{t \in \mathcal{T}} |\hat{F}_X\cdot(t) - \tilde{F}_X\cdot(t)| = o_p(n^{-c}).$$

**Proof.** Since the proof is similar, we only present the proof for the ordinary smooth case. For simplicity, we restrict attention to the case of $N_i = 2$. For more general situations where $N_i$ is arbitrary but bounded above by $C$, the proof follows by similar arguments after accounting for the dependence structure in $\hat{F}_X\cdot$. 

26
We first make the following preliminary observations. Note that \( \hat{F}_{X^*}(t) \) can be alternatively written as
\[
\hat{F}_{X^*}(t) = \frac{1}{2\pi} \int_{-1/h}^{1/h} \text{Im}\left\{ e^{i\omega t} \hat{f}_X^h(\omega) \right\} K^h(h\omega) d\omega.
\] (32)
where \( \hat{f}_X^h(\omega) = N^{-1} \sum_{i,j} e^{i\omega X_{i,j}} \) denotes the empirical characteristic function. A similar expression holds for \( \hat{F}_{X^*} \). Let \( \xi = (f^h)^2 \) and \( \hat{\xi} = (\hat{f}_\xi)^2 \). Recall that \( \xi \) and \( \hat{\xi} \) are the population and empirical Fourier transforms of \( X_{i,j1} - X_{i,j2} \). We note the following properties for \( \hat{\xi} \)
\[
E \left[ \int_{-\infty}^{\infty} \omega^{-a} |\hat{\xi}(\omega) - \xi(\omega)|^2 d\omega \right] = \begin{cases} n^{-1} h^{-1-a} & \text{if } a < 1 \\ n^{-1} & \text{if } a > 1 \\ n^{-1} \log(1/h) & \text{if } a = 1 \end{cases} (33)
\]
\[
\sup_{|\omega| \leq h^{-1}} |\xi/\hat{\xi}| \leq 1 + o_p(1). (34)
\]
The results in (33) can be shown by expanding the expectations. To show (34), we use Yuki-\( \text{c} \)h (1987, Theorem 6.3) which assures that under Assumption B (i), \( \sup_{|\omega| \leq h^{-1}} |\hat{\xi} - \xi| = O_p(\sqrt{\log n/n}) \) for \( h = O(n^{-c}) \) with some \( c > 0 \). Combined with Assumption B (ii), this implies \( \{\min_{|\omega| \leq h^{-1}} |\hat{\xi}|\}^{-1} = O_p(h^{-2\beta}) \). Thus we obtain
\[
\sup_{|\omega| \leq h^{-1}} |\xi/\hat{\xi}| \leq 1 + \sup_{|\omega| \leq h^{-1}} |(\hat{\xi} - \xi)/\hat{\xi}| = 1 + O_p \left( \left( \frac{\log n}{nh^{4\beta}} \right)^{1/2} \right) = 1 + o_p(1),
\]
thereby proving (34).

Pick any \( \eta \in (1/2, \gamma - \beta) \). Under Assumptions C (iii) and OS (i), it can be verified that
\[
\int_{-1/h}^{1/h} \left| \frac{\omega^n f^h_X(\omega)}{\xi(\omega)^{1/2}} \right|^2 d\omega = O(1). (35)
\]
We shall also make frequent use of the following algebraic inequality:
\[
|\hat{\xi}^{1/2} - \xi^{1/2}| \leq \xi^{-1/2} |\xi - \hat{\xi}|. (36)
\]
We now proceed to the main part of the proof. By (32), we can expand
\[
\hat{F}_{X^*}(t) - \hat{F}_{X^*}(t) = \frac{1}{2\pi} \int_{-1/h}^{1/h} \text{Im}\left\{ \frac{e^{i\omega t} \hat{f}_X^h(\omega)}{-\omega} \right\} \{ \hat{\xi}(\omega)^{-1/2} - \xi(\omega)^{-1/2} \} K^h(h\omega) d\omega
\]
\[
+ \frac{1}{\pi} \int_{-1/h}^{1/h} \text{Im}\left\{ \frac{e^{i\omega t} \hat{f}_X^h(\omega)}{-\omega} \right\} \{ \hat{\xi}(\omega)^{-1/2} - \xi(\omega)^{-1/2} \} K^h(h\omega) d\omega
\]
\[
= B_{1n}(t) + B_{2n}(t).
\]
For the term \( B_{1n}(t) \), using (36), we have
\[
|B_{1n}(t)| \leq \frac{1}{\pi} \int_{0}^{\infty} \left| \text{Im}\left\{ \frac{e^{i\omega t} \hat{f}_X^h(\omega)}{-\omega} \right\} \right| \left| \xi(\omega)^{1/2} \right| \left| \hat{\xi}(\omega) - \xi(\omega) \right| |\xi(\omega)|^{-3/2} d\omega.
\]
By the fact \( \sup_{|\omega| \leq \omega_0} |\hat{\xi} - \xi| = O_p(n^{-1/2}) \) and (34), we obtain
\[
\sup_{t \in T} |B_{1n}(t)| = O_p(n^{-1/2}) \sup_{t \in T} I(t),
\]
where
where

\[ I(t) = \int_0^{\omega_0} \left| \frac{\text{Im}\{e^{-i\omega t} \hat{f}_X^B(\omega)\}}{-\omega} \right| d\omega \]

\[ \leq \int_0^{\omega_0} \frac{\sin(\omega t)}{\omega} \text{Re}\{ \hat{f}_X^B(\omega) \} \left| d\omega + \int_0^{\omega_0} \frac{\cos(\omega t)}{\omega} \text{Im}\{ \hat{f}_X^B(\omega) \} \left| d\omega \right. \right. \]

\[ = I_1(t) + I_2. \]

Since \( T \) is a compact set, it holds \( \sup_{t \in T} I_1(t) < \infty \). By the definition of \( \hat{f}_X^B \), the random variable \( I_2 \) can be bounded as

\[ I_2 \leq \frac{1}{N} \sum_{i,j} \int_0^{\omega_0} \left| \frac{\sin(\omega X_{i,j})}{\omega} \right| d\omega = \frac{1}{N} \sum_{i,j} T_{i,j}. \]

Since

\[ E[T_{i,j}] = E \int_0^{\omega_0} \frac{\sin(\omega t)}{t} dt \leq C_1 + E[|X_{i,j}|] < \infty \]

for some \( C_1 > 0 \), it holds \( I_2 = O_p(1) \). Combining these results, we obtain \( \sup_{t \in T} |B_{1n}(t)| = O_p(n^{-1/2}). \)

For the term \( B_{2n}(t) \), we further expand

\[ B_{2n}(t) = -\frac{1}{\pi} \int_0^{1/h} \frac{\text{Im}\{e^{-i\omega t} \hat{f}_X^B(\omega)\}}{-\omega \xi(\omega)^{1/2}} \{ \xi(\omega)^{1/2} - \xi(\omega)^{1/2} \} K^B(h\omega) \xi(\omega)^{1/2} d\omega \]

\[ + \frac{1}{\pi} \int_0^{1/h} \frac{\text{Im}\{e^{-i\omega t} \hat{f}_X^B(\omega) - \hat{f}_X^B(\omega)\}}{-\omega} \{ \xi(\omega)^{-1/2} - \xi(\omega)^{-1/2} \} K^B(h\omega) d\omega \]

\[ = B_{21n}(t) + B_{22n}(t). \]

For the term \( B_{21n}(t) \), we have

\[ \sup_{t \in T} |B_{21n}(t)| \leq \frac{1}{\pi} \int_0^{1/h} \frac{\omega \eta \xi(\omega)}{\xi(\omega)^{1/2}} \left| \frac{\hat{\xi}(\omega) - \xi(\omega)}{\omega^{1+\eta} \xi(\omega)^{1/2}} \right| \left| \frac{\xi(\omega)^{1/2}}{\xi(\omega)} \right| d\omega \]

\[ \leq C_2 (1 + o_p(1)) \left( \int_0^{1/h} \omega^\eta \xi(\omega) d\omega \right)^{1/2} \left( \int_0^{1/h} \omega^{2(\beta-\eta-1)} |\hat{\xi}(\omega) - \xi(\omega)|^2 d\omega \right)^{1/2} \]

\[ = O(n^{-1/2} h^{(\eta-\beta+1/2)^0}), \]

for some \( C_2 > 0 \), where the first inequality follows from the fact \( |\text{Im}\{e^{-i\omega t} \hat{f}_X^B(\omega)\}| \leq |\hat{f}_X^B(\omega)| = |\hat{f}_X^B(\omega)| \xi(\omega)^{1/2} \) and (36), the second inequality follows from (34) and Assumption OS (i), and the equality follows from (33) and (35).

Now consider the term \( B_{22n}(t) \). Applying (36) and Assumption OS (i), we can write

\[ \sup_{t \in T} |B_{22n}(t)| \leq \frac{1}{\pi} \int_0^{1/h} |\hat{f}_X^B(\omega) - \hat{f}_X^B(\omega)| |\hat{\xi}(\omega) - \xi(\omega)| \xi(\omega)^{1/2} / \omega \xi(\omega)^{3/2} d\omega \]

\[ \leq \frac{1}{\pi^3} \int_0^{1/h} |\hat{f}_X^B(\omega) - \hat{f}_X^B(\omega)| |\xi(\omega) - \xi(\omega)| \xi(\omega)^{1/2} \omega^{3\beta-1} d\omega, \]
So, the bias term is negligible and it is enough to show that
\[ \text{Lemma 2.} \]
\[ B.2. \]
Lemmas for Theorem 2 under Assumption OS (i)-(iii).

\[
\text{Then } (37) \text{ is rewritten as } \\
E \left[ \int_{\omega_0}^{1/h} \omega^{-a} |\hat{F}_X(\omega) - f_X(\omega)|^2 d\omega \right] = O((nh^{1-a})^{-1}),
\]
for all \( a < 1 \). Thus, by (34) and (35), it follows
\[
\sup_{t \in T} |B_{22n}(t)| \leq \frac{1 + o_p(1)}{\pi} \int_{\omega_0}^{1/h} \omega^{3\beta-1} |\hat{F}_X(\omega) - f_X(\omega)|^2 d\omega \div (\int_{\omega_0}^{1/h} \omega^{3\beta-1} \xi(\omega)^2 d\omega)^{1/2} = O((nh^{3\beta})^{-1}).
\]
Combining these results, we obtain
\[
\sqrt{nh^{\beta-1/2}} \sup_{t \in T} |\hat{F}_X(\omega) - F_X(\omega)| = O_p \left( h^{(\eta + (\beta - 1)/2)} + \frac{1}{\sqrt{nh^{2\beta + 1/2}}} \right) = o_p(n^{-c})
\]
for some \( c > 0 \), under Assumptions OS (iii), B (ii) and the condition \( \eta > 1/2 \).

\[ \square \]

### B.2. Lemmas for Theorem 2 under Assumption OS (i)-(iii).

**Lemma 2.** Under Assumptions C (i)-(iv) and OS (i)-(iii), there exist sequences \( \epsilon_n, \delta_n = O(n^{-c}) \) for some \( c > 0 \) such that
\[
P \left\{ \sup_{t \in T} \left| \sqrt{nh^{\beta-1/2}} \{ \hat{F}_X(\omega) - F_X(\omega) \} - \mathcal{G}_n(\omega) \right| > \epsilon_n \right\} < \delta_n.
\]

**Proof.** By applying the argument in Hall and Lahiri (2008), the bias of the estimator \( \hat{F}_X \) satisfies \( \sup_{t \in T} |E[\hat{F}_X(t)] - F_X(t)| = O(h^\gamma) \). Thus, Assumption OS (iii) guarantees
\[
\sqrt{nh^{\beta-1/2}} \sup_{t \in T} |E[\hat{F}_X(t)] - F_X(t)| = o(n^{-\xi}).
\]
So, the bias term is negligible and it is enough to show that
\[
P \left\{ \sup_{t \in T} \left| \sqrt{nh^{\beta-1/2}} \{ \hat{F}_X(\omega) - E[\hat{F}_X(\omega)] \} - \mathcal{G}_n(\omega) \right| > \epsilon_n \right\} < \delta_n,
\]
for some \( \epsilon_n, \delta_n = O(n^{-c}) \) with \( c > 0 \). Let \( F_{X,n}^{EDF} \) be the empirical distribution function by \( \{X_i\}_{i=1}^n, \alpha_n(x) = \sqrt{n} \{ F_{X,n}^{EDF}(x) - F_X(x) \} \) be the empirical process, and
\[
D_n(t) = \sqrt{nh^{\beta-1/2}} \{ \hat{F}_X(\omega) - E[\hat{F}_X(\omega)] \} = h^{\beta-1/2} \int \mathbb{L} \left( \frac{t - a}{h} \right) d\alpha_n(a).
\]
Then (37) is rewritten as
\[
P \left\{ \sup_{t \in T} |D_n(t)| - \mathcal{G}_n(\omega) \right\} > \epsilon_n \right\} < \delta_n,
\]
for some \( \epsilon_n, \delta_n = O(n^{-c}) \) with \( c > 0 \).

First, we approximate \( D_n(t) \) by
\[
D_{n,0}(t) = h^{\beta-1/2} \int \mathbb{L} \left( \frac{t - a}{h} \right) d\alpha_n(a),
\]
for some
Note that both $D_n(t)$ and $D_{n,0}(t)$ are well defined as Lebesgue-Stieltjes integrals. From integration by parts,
\[
D_n(t) = h^{\beta-3/2} \int \mathbb{K}\left(\frac{t-a}{h}\right) \alpha_n(a) da
+ h^{\beta-1/2} \lim_{a \to \infty} \left\{ \mathbb{L}\left(\frac{t-a}{h}\right) \alpha_n(a) \right\} - h^{\beta-1/2} \lim_{a \to -\infty} \left\{ \mathbb{L}\left(\frac{t-a}{h}\right) \alpha_n(a) \right\}
= h^{\beta-3/2} \int \mathbb{K}\left(\frac{t-a}{h}\right) \alpha_n(a) da,
\]
for all $n \in \mathbb{N}$, where the second equality follows from the facts $\lim_{a \to \pm \infty} \alpha_n(a) = 0$ and $\sup_u |\mathbb{L}(u)| < \infty$ for each $h$. Since a similar expression applies for $D_{n,0}(t)$, there exists $C > 0$ such that
\[
D_n(t) - D_{n,0}(t) = h^{\beta-1/2} \int \{ \mathbb{K}(u) - \mathbb{K}(u) \} \alpha_n(u - th) du \leq Ch^{s} \sup_u |\alpha_n(u)|,
\]
for all $n$ large enough and $t \in T$, where the inequality follows from Assumption OS (ii). Now by the strong approximation (Komlós, Major and Tusnády, 1975), there exists a tight Brownian bridge $B(t) = W(t) - tW(1)$ and universal constants $C_1, C_2 > 0$ such that
\[
P\left\{ \sup_u |\alpha_n(u)| \leq \sup_u |B(F_X(u))| + C_1 \frac{\log n}{\sqrt{n}} \right\} \geq 1 - \frac{C_2}{n},
\]
for all $n \in \mathbb{N}$. Combining these results and using the properties of $\sup_u |B(F_X(u))|$ (in particular, $P\{\sup_u |B(F_X(u))| \geq x\} \leq 2 \exp(-2x^2)$ for $x > 0$), there exists $C_3 > 0$ such that
\[
P\left\{ \sup_{t \in T} |D_n(t) - D_{n,0}(t)| > h^{s/2} \right\} \leq C_3 \exp(-2h^{-s}) + \frac{C_2}{n},
\]
for all $n$ large enough. Note that $h^{s/2} = O(n^{-c})$ for some $c_1 > 0$ due to Assumption OS (iii) ($n^c h \to 0$). Thus, it is enough for (38) to show that
\[
P\left\{ \sup_{t \in T} |D_n(t) - G_n(t)| > \epsilon_n \right\} < \delta_n,
\]
for some $\epsilon_n, \delta_n = O(n^{-c})$ with $c > 0$.

Second, we approximate $D_{n,0}(t)$ by
\[
D_{n,1}(t) = h^{\beta-1/2} \int \mathbb{L}\left(\frac{t-a}{h}\right) dB(F_X(a)).
\]
Since $\mathbb{L} \in L_2(\mathbb{R})$, this integral exists for all $t \in \mathbb{R}$. Analogous to the integration by parts formula in (39), a similar result applies for $D_{n,1}(t)$ based on stochastic integration by parts using the facts $\lim_{u \to \pm \infty} \mathbb{L}(u) = 0$ and $\sup_a |B(F_X(a))| < \infty$ almost surely. Thus, we have
\[
D_{n,0}(t) - D_{n,1}(t) = h^{\beta-3/2} \int \mathbb{K}\left(\frac{t-a}{h}\right) \{ \alpha_n(a) - B(F_X(a)) \} da
\leq h^{\beta-1/2} \sup_a |\alpha_n(a) - B(F_X(a))| \int |\mathbb{K}(u)| du.
\]

---

9 This is verified as follows. By the definition $\mathbb{L}(u) = \int_0^u \mathbb{K}(v) dv$ and Assumption OS (ii), we have $\sup_u |\mathbb{L}(u)| < \infty$. Also, by $\mathbb{L}(u) = \int_0^u \mathbb{K}(v) dv$ (follows from Fubini’s theorem) and Assumption OS (ii), we have $\sup_u |\mathbb{L}(u)| < \infty$. Therefore, bounded variation of the empirical process $\alpha_n$ guarantees that both $D_n(t)$ and $D_{n,0}(t)$ are well defined.
for all \( n \in \mathbb{N} \), almost surely. Now by Komlós, Major and Tusnády (1975), there exist Brownian bridge \( B \) with continuous sample paths and universal constants \( C_4, C_5 > 0 \) such that

\[
P\left\{ \sup_{a \in \mathbb{R}} |\alpha_n(a) - B(F_X(a))| > C_4 \frac{\log n}{\sqrt{n}} \right\} \leq \frac{C_5}{n},
\]

for all \( n \in \mathbb{N} \). Combining this with Assumption OS (ii) (eq. (9)), there exist \( c_2, C_6 > 0 \) such that

\[
P\left\{ \sup_{t \in T} |D_{n,0}(t) - D_{n,1}(t)| > C_6 n^{-c_2} \right\} \leq \frac{C_5}{n},
\]

for all \( n \) large enough. Thus, it is enough for (38) to show that

\[
P\left\{ \sup_{t \in T} |D_{n,1}(t) - \mathcal{G}_n(t)| > \epsilon_n \right\} < \delta_n,
\]

for some \( \epsilon_n, \delta_n = O(n^{-c}) \) with \( c > 0 \).

Third, we approximate \( D_{n,1}(t) \) by

\[
D_{n,2}(t) = h^{\beta-1/2} \int \mathbb{L} \left( \frac{t - a}{h} \right) dW(F_X(a)).
\]

By the definition \( B(t) = W(t) - tW(1) \), we have

\[
|D_{n,1}(t) - D_{n,2}(t)| \leq h^{\beta-1/2}|W(1)| \left| \int \mathbb{L} \left( \frac{t - a}{h} \right) f_X(a) da \right|,
\]

for all \( n \in \mathbb{N} \). Therefore, for the rate of \( \sup_{t \in T} |D_{n,1}(t) - D_{n,2}(t)| \), we need to characterize the order of \( I_{n,1}(t) = \int \mathbb{L} \left( \frac{t - a}{h} \right) f_X(a) da \). By the definition of \( \mathbb{L} \) and

\[
\int_{-\infty}^{\infty} \sin(\omega(t - a)) f_X(a) da = \frac{1}{2i} \left\{ e^{i\omega \xi} f_{\xi}^{\text{th}}(\omega) - e^{-i\omega \xi} f_{\xi}^{\text{th}}(\omega) \right\},
\]

an application of Fubini’s theorem assures

\[
|I_{n,1}(t)| = \left| \frac{1}{2i\pi} \int_{\omega_0}^{1/h} \left\{ e^{i\omega \xi} f_{\xi}^{\text{th}}(\omega) - e^{-i\omega \xi} f_{\xi}^{\text{th}}(\omega) \right\} \frac{K_1(\xi h\omega)}{\omega f_{\xi}^{\text{th}}(\omega)} d\omega \right|
\]

\[
\leq \frac{1}{\pi} \int_{\omega_0}^{1/h} \omega^{-1} d\omega = O(\log(1/h)),
\]

where the inequality follows from \( |f_{\xi}^{\text{th}}| = |f_{\xi}^{\text{th}}|^1|f_{\xi}^{\text{th}}| \leq |f_{\xi}^{\text{th}}| \) and \( f_{\xi}^{\text{th}}(\omega) = f_{\xi}^{\text{th}}(\omega) \). Substituting this bound for \( I_{n,1}(t) \) into (40), we obtain

\[
P\left\{ \sup_{t \in T} |D_{n,1}(t) - D_{n,2}(t)| > M_n h^{\beta-1/2} \log(1/h) \right\} = O(n^{-c_3}),
\]

for some \( c_3 > 0 \) and sequence \( M_n = \log n \). By Assumption OS (i) \( (\beta > 1/2) \), it holds \( M_n h^{\beta-1/2} \log(1/h) = O(n^{-c_4}) \) for some \( c_4 > 0 \). Therefore, it is enough for (38) to show that

\[
P\left\{ \sup_{t \in T} |D_{n,2}(t) - \mathcal{G}_n(t)| > \epsilon_n \right\} < \delta_n,
\]

for some \( \epsilon_n, \delta_n = O(n^{-c}) \) with \( c > 0 \). But we can see that the process \( D_{n,2}(t) \) has the same finite dimensional distributions as the process \( \mathcal{G}_n(t) \). Therefore, this trivially holds true and the conclusion is obtained.
Lemma 3. Under Assumptions C (i)-(iv) and OS (i)-(iii), there exist sequences $\epsilon_n, \delta_n, \delta_2 = O(n^{-c})$ for some $c > 0$ such that with probability greater than $1 - \delta_2$, 

$$P^\# \left\{ \sup_{t \in T} \sqrt{n} \left| \bar{F}_{X_n}^\#(t) - \tilde{F}_{X_n}^\#(t) \right| > \epsilon_n \right\} \leq \frac{C_1}{n},$$

where $\tilde{G}_n$ is a tight Gaussian process with the same distribution as $G_n$ under $P^\#$.

Proof. The proof is essentially a reformulation of that of Bissantz, Dümbgen, Holzmann and Munk (2007, Theorem 2.1). Let $\alpha_n^\#(t) = \sqrt{n} \left\{ F_{X_n}^\# - F_{X_n}^{\text{EDF}}(t) \right\}$ denote the bootstrap empirical process. As shown in the proof of Bissantz, Dümbgen, Holzmann and Munk (2007, eq. (21)), based on Shorack (1982), there exist a Brownian bridge $B_n^\#$ and universal constants $C, C_1 > 0$ such that for all $n \in \mathbb{N}$,

$$P^\# \left\{ \sup_{t \in \mathbb{R}} |\alpha_n^\#(t) - B_n^\#(F_{X_n}^\#(t))| > C \frac{\log n}{\sqrt{n}} \right\} \leq \frac{C_1}{n},$$

almost surely. Now it is known that the Brownian bridge is Hölder continuous for every exponent $b \in (0, 1/2)$ almost surely. Furthermore, by Komlós, Major and Tusnády’s (1975) coupling, along with the fact $P\{ \sup_t |B(F_X(t))| \geq \log n \} \leq 2 \exp(-2(\log n)^2)$, there exist universal constants $C_2, C_3 > 0$ such that

$$P \left\{ \sup_{t \in \mathbb{T}} |F_{X_n}^{\text{EDF}}(t) - F_X(t)| > C_2 \frac{\log n}{\sqrt{n}} \right\} \leq \frac{C_3}{n},$$

for all $n \in \mathbb{N}$, which consequently implies

$$P \left\{ \sup_{t \in \mathbb{T}} |B_n^\#(F_{X_n}^{\text{EDF}}(t)) - B_n^\#(F_X(t))| > C_4 \frac{\log n}{n^{b/2}} \right\} \leq \frac{C_5}{n},$$

for some universal constants $C_4, C_5 > 0$. Combining these results, there exist universal constants $C_6, C_7, C_8 > 0$ such that with probability greater than $1 - C_6/n$, it holds

$$P^\# \left\{ \sup_{t \in \mathbb{T}} |\alpha_n^\#(t) - B_n^\#(F_X(t))| > C_7 \frac{\log n}{n^{b/2}} \right\} \leq \frac{C_8}{n},$$

for all $n \in \mathbb{N}$. Based on this, the conclusion follows by similar arguments to the proof of Lemma 2. \hfill \square

Lemma 4. Suppose that Assumptions C (i)-(iv) and OS (i)-(iii) hold true. Then for any sequence $\epsilon_n = O(n^{-c})$ with $c > 0$, there exists a constant $M > 0$ such that

$$p_{\epsilon_n}(G_n) \leq M \epsilon_n \sqrt{\log(1/h)},$$

for all $n$ large enough.

Proof. Pick any $\epsilon > 0$. By Chernozhukov, Chetverikov and Kato (2015, Theorem 3) and separability of $G_n$, there exists $C > 0$ such that

$$p_{\epsilon}(G_n) \leq C \epsilon \left\{ \sigma_n^{-1} E \left[ \sup_{t \in T} |G_n(t)| \right] + \sqrt{1 \vee \log(G_n/\epsilon)} \right\},$$
for all \( n \in \mathbb{N} \). Thus, it is enough to show that
\[
E \left[ \sup_{t \in T} |G_n(t)| \right] = O(\sqrt{\log(1/\delta)}).
\]
Now,
\[
d_n^2(s, t) = h^{2\beta} \int \left\{ \tilde{\mathbb{L}} \left( \frac{s}{h} - a \right) - \tilde{\mathbb{L}} \left( \frac{t}{h} - a \right) \right\}^2 f_X(ha) \, da
\]
by the Itô isometry. Note that \( \tilde{\mathbb{L}} \) is Lipschitz continuous because its derivative \( \tilde{\mathbb{K}} \) is uniformly bounded on \( \mathbb{R} \) (because \( h^{\beta} \sup_{n} |\tilde{\mathbb{K}}(u)| \leq C \) for some \( C > 0 \) by Assumption OS (i)). Thus, it holds
\[
d_n(s, t) \leq C_1 h^{-3/2}|s - t|,
\] (41)
for some \( C_1 > 0 \) that is independent of \( s \) and \( t \).

Let \( D(\varepsilon, d_n) \) be the \( \varepsilon \)-packing number for the set \( T \) under the sub-metric \( d_n \). By (41), it holds
\[
D(\varepsilon, d_n) \leq 2C_1 h^{-3/2}/\varepsilon.
\]
Pick any \( \delta \in (0, 1) \). By van der Vaart and Wellner (1996, Corollary 2.2.8), there exist universal constants \( C_2, C_3 > 0 \) such that
\[
E \left[ \sup_{d_n(s, t) \leq \delta} |G_n(s) - G_n(t)| \right] \leq C_2 \delta \sqrt{\log(2C_1 h^{-3/2})} + C_2 \int_0^\delta \sqrt{\log(1/\varepsilon)} d\varepsilon \leq C_3 \sqrt{\log(1/\delta)},
\]
for all \( n \in \mathbb{N} \). Thus, by the above and (41), there exists a collection of Gaussian random variables \( \{G_n(t_j)\}_{j=1}^{P_n} \) with \( p_n = \left\lfloor \frac{1}{h^{3/2}\delta} \right\rfloor \) such that
\[
E \left[ \sup_{t \in T} |G_n(t)| \right] \leq E \left[ \max_{1 \leq j \leq p_n} |G_n(t_j)| \right] + C_3 \sqrt{\log(1/\delta)},
\]
for all \( n \in \mathbb{N} \). Now the properties of the maximum of Gaussian random variables yields
\[
E \left[ \max_{1 \leq j \leq p_n} |G_n(t_j)| \right] \leq 2\sigma_n \sqrt{1 + \log p_n}.
\]
Combining these results, the conclusion follows. \( \square \)

B.3. Lemmas for Theorem 2 under Assumption SS (i)-(iii).

Lemma 5. Under Assumptions C (i)-(iv) and SS (i)-(iii), there exist sequences \( \varepsilon_n = O(\log n)^{-1+c} \) and \( \delta_n = O(n^{-c}) \) with \( c > 0 \) such that
\[
P \left\{ \sup_{t \in T} \left| \frac{\sqrt{n}}{\delta(h)} \{ \tilde{F}_X(t) - F_X(t) \} - G_n(t) \right| > \varepsilon_n \right\} < \delta_n.
\]

Lemma 6. Under Assumptions C (i)-(iv) and SS (i)-(iii), there exist sequences \( \varepsilon_{1n}, \delta_{1n}, \delta_{2n} = O(n^{-c}) \) with \( c > 0 \) such that with probability greater than \( 1 - \delta_{2n} \),
\[
P^\# \left\{ \sup_{t \in T} \left| \frac{\sqrt{n}}{\delta(h)} \{ \tilde{F}_X(t) - F_X(t) \} - \tilde{G}_n(t) \right| > \varepsilon_{1n} \right\} < \delta_{1n},
\]
where \( \tilde{G}_n \) is a tight Gaussian process with the same distributions as \( G_n \) under \( P^\# \).

These lemmas can be shown in the same way as Lemmas 2 and 3. The log rate of \( \varepsilon_n \) in Lemma 5 is due to the bias term. Recall that under Assumption C (ii), the bias of the estimator
$F_{X^*}$ is given by

$$\sup_{t \in T} |E[\tilde{F}_{X^*}(t)] - F_{X^*}(t)| = O(h^\gamma).$$

Then due to Assumption SS (iii), it holds $\sqrt{n}h^\gamma / \zeta(h) = C(\log n)^{-c}$ for some $c > 1$.

**Lemma 7.** Suppose that Assumptions C (i)-(iv) and SS (i)-(iii) hold true. Then for any sequence $\epsilon_n = O(\log n)^{-c}$ with $c > 1$ there exists $M > 0$ such that

$$p_{\epsilon_n}(G_n) \leq M\epsilon_n (\log n)^{1+r},$$

for all $n$ large enough and any $r > 0$ independent of $n$.

**Proof.** Pick any $\varepsilon > 0$. By Chernozhukov, Chetverikov and Kato (2015, Theorem 3) and separability of the Gaussian process $G_n$, there exists $C > 0$ such that

$$p_\epsilon(G_n) \leq C\varepsilon \left\{ \sigma_n^{-1} E \left[ \sup_{t \in T} |G_n(t)| \right] + \sqrt{1 \lor \log(G_n/\varepsilon)} \right\},$$

for all $n \in \mathbb{N}$. By Lemmas 8 and 9 shown below, the following hold true:

- there exist $c_1 > 0$ such that $\sigma_n \geq c_1 h^{\lambda+\nu}$ for all $\nu > 0$ and $n$ large enough, \hspace{1cm} (42)
- there exist $C_1 > 0$ such that $\sigma_n \leq C_1$ for all $n$ large enough. \hspace{1cm} (43)

Observe that

$$d_n^2(s,t) = \frac{h}{\zeta^2(h)} \int \left\{ \tilde{L} \left( \frac{s}{h} - a \right) - \tilde{L} \left( \frac{t}{h} - a \right) \right\}^2 f_X(ha) da$$

by the Ito isometry. Note that $\tilde{L}$ is Lipschitz continuous because its derivative $\tilde{K}$ is uniformly bounded on $\mathbb{R}$ (because $\sqrt{h}\zeta^{-1}(h) \sup_u |\tilde{K}(u)| \leq C_2 h^{-c_2}$ for some $C_2, c_2 > 0$ by Assumption SS (i)). Thus, it holds $d_n(s,t) \leq C_3 h^{-c_2 - 3/2} |s - t|$ for some $C_3 > 0$ that is independent of $s$ and $t$.

Using (43), an analogous argument as in the proof of Lemma 4 shows that $E[\sup_{t \in T} |G_n(t)|] = O(\sqrt{\log(1/h)})$. Combining this with (42) and Assumption SS (iii), the conclusion follows. \hspace{1cm} \Box

**Lemma 8.** Under Assumptions C (i)-(iv) and SS (i)-(iii), there exists $c > 0$ such that $\sigma_n \geq ch^{\lambda+\nu}$ for all $\nu > 0$ and $n$ large enough.

**Proof.** We only prove the case of $\lambda_0 \geq 0$. The proof for the case of $\lambda_0 < 0$ is similar. Pick any $\varepsilon > 0$. By Assumption C (i), we provide a lower bound for $\sigma_n$ via

$$\sigma_n = \inf_{t \in T} \frac{h}{\zeta^2(h)} \int \tilde{L}^2(a) f_X(t - ha) da \geq \frac{c_1 h}{\zeta^2(h)} \int_{|a| \leq h^\varepsilon} \tilde{L}^2(a) da,$$

for some $c_1 > 0$. Let

$$\Phi_\varepsilon(\omega) = f_\varepsilon^\omega (\omega)^{-1} \{ |\omega| \geq \omega_0 \}.$$

Using the fact $\sin(x) = x + R(x)$ with $|R(x)| \leq c_2 |x|^2$ for some $c_2 > 0$, it follows that for all $|a| \leq h^\varepsilon$,

$$|\tilde{L}(a)| \geq \frac{1}{\pi} \int_0^1 K^0(\omega) \Phi_\varepsilon \left( \frac{\omega}{h} \right) d\omega - \frac{c_2}{\pi} \int_0^1 |a\omega| K^0(\omega) \Phi_\varepsilon \left( \frac{\omega}{h} \right) d\omega \geq C_1 \int |a\omega| K^0(\omega) \Phi_\varepsilon \left( \frac{\omega}{h} \right) d\omega \geq C \lambda \int |a| I_n |\omega| \Phi_\varepsilon \left( \frac{\omega}{h} \right) d\omega,$$

where $I_n = \int_0^1 K^0(\omega) \Phi_\varepsilon \left( \frac{\omega}{h} \right) d\omega$. The last inequality follows from the fact $\sup\{|a\omega| : |a| \leq h^\varepsilon, \omega \in [0,1] \} = h^\varepsilon$. 

34
We now provide a lower bound for $I_n$. Pick any $\delta > 0$. Observe that
\[
\begin{align*}
  h^{-\frac{3}{2}}\zeta(h)^{-\frac{1}{2}}|I_n| &= \exp(-1/\mu h) \frac{c_3}{h^\lambda(r+1)+\lambda_0} \int_{h\omega_0}^1 K^\delta(\omega)\Phi_\epsilon\left(\frac{\omega}{h}\right) d\omega \\
  &\geq c_3 \exp(-1/\mu h) \frac{c_3}{h^\lambda(r+1)} \int_{h\omega_0}^1 K^\delta(\omega)\omega^{-\lambda_0} \exp\left(\frac{\omega^\lambda}{h^\lambda\mu}\right) d\omega \\
  &\geq c_3 \exp(-1/\mu h) \frac{c_3}{h^\lambda(r+1)} \int_0^1 K^\delta(\omega) \exp\left(\frac{\omega^\lambda h}{h^\lambda\mu}\right) d\omega \\
  &= c_3 \int_0^{\frac{1}{1-\delta}h^{-\lambda}} K^\delta\left(\frac{1-h^\lambda v}{h^\lambda v}\right)v^r \exp\left(\frac{1-h^\lambda v^\lambda - 1}{h^\lambda\mu}\right) dv \leq c_3 \int v^r \exp(-\lambda v/\mu) dv > 0,
\end{align*}
\]
for some $c_3 > 0$, where the first inequality follows from the fact $\Phi_\epsilon(\omega) \geq c_3|\omega|^{-\lambda_0} \exp(|\omega^\lambda/\mu|)$, the second inequality holds since all the terms inside the integral are positive and $\omega^{-\lambda_0}\{h\omega_0 \leq \omega \leq 1\} \geq 1$ for $\lambda_0 \geq 0$, the second equality follows from a change of variables, and the convergence follows from the dominated convergence theorem after noting
\[
\frac{K^\delta(1-h^\lambda v)}{(h^\lambda v)^r}v^r \exp\left(\frac{1-h^\lambda v^\lambda - 1}{h^\lambda\mu}\right) \{0 \leq v \leq (1-\delta)h^{-\lambda}\} \\
\leq \begin{cases} 
  \sup_{0 \leq t \leq 1}\{t^{-r}K^\delta(1-t)\} v^r \exp(-v/\mu) & \text{if } \lambda \geq 1, \\
  \sup_{0 \leq t \leq 1}\{t^{-r}K^\delta(1-t)\} v^r \exp(-\lambda v/\mu) & \text{if } 0 < \lambda < 1.
\end{cases}
\]
Thus, it holds $h^{1/2}\zeta(h)^{-1/2}|I_n| > c_3 h^{\lambda/2}$ for all $n$ large enough.

Combining these results, there exists $c > 0$ such that
\[
\sigma_n \geq c h^\lambda \int_{|a| \leq h^\varepsilon} |a|^2 da \geq c h^{\lambda+3\varepsilon},
\]
for all $n$ large enough, and the conclusion follows. \(\square\)

**Lemma 9.** Under Assumptions C (i)-(iv) and SS (i)-(iii), there exists $C > 0$ such that $\sigma_n \leq C$ for all $n$ large enough.

**Proof.** We only prove the case of $\lambda_0 \geq 0$. The proof for the case of $\lambda_0 < 0$ is similar. Pick any $\varepsilon \in (0, 2^{-1/\lambda})$. Since $f_X$ is bounded (Assumption C (ii)), there exists $C_1, C_2 > 0$ such that
\[
\begin{align*}
  \sigma_n &\leq C_1 \exp\left(-2/\mu h^\lambda\right) \int I(a) da = C_2 \exp\left(-2/\mu h^\lambda\right) \int_{h\omega_0}^1 \left| K^\delta(\omega)\Phi_\epsilon\left(\frac{\omega}{h}\right) \right|^2 d\omega \\
  &\leq C_2 \omega^{-2}_{0} \exp\left(-2/\mu h^\lambda\right) \int_{h\omega_0}^1 \left| K^\delta(\omega)\Phi_\epsilon\left(\frac{\omega}{h}\right) \right|^2 d\omega \\
  &\leq C_2 \omega^{-2}_{0} \exp\left(-2/\mu h^\lambda\right) \int_{h\omega_0}^{\varepsilon} \left| K^\delta(\omega)\Phi_\epsilon\left(\frac{\omega}{h}\right) \right|^2 d\omega \\
  &\quad + C_2 \omega^{-2}_{0} \exp\left(-2/\mu h^\lambda\right) \int_{|\omega| > \varepsilon} \left| K^\delta(\omega)\omega^{-(1+\lambda_0)} \exp\left(\frac{|\omega^\lambda}{h^\lambda\mu}\right) \right|^2 d\omega \\
  &= T_{1n} + T_{2n},
\end{align*}
\]
for all $n$ large enough, where the first equality follows from Plancherel’s isometry, and the second inequality follows from $\Phi_{\epsilon}(\omega) \leq C|\omega|^{-\lambda_0} \exp(|\omega|^\lambda/\mu)$. For $T_{1n}$, Assumption SS (iii) and the restriction $\epsilon \in (0, 2^{-1/\lambda})$ guarantee

$$T_{1n} \leq C_3 \omega_0^{-(1+\lambda_0)} \frac{\exp(-2/\mu h^\lambda)}{h^{(2r+1)+2(1+\lambda_0)}} \int_{h\omega_0}^\infty |K^{\beta}(\omega)| \exp \left( \frac{|\omega|^\lambda}{h^\lambda \mu} \right) d\omega,$$

$$\leq C_4 \frac{\exp(-1/\mu h^\lambda)}{h^{(2r+1)+2(1+\lambda_0)}} = O(n^{-c_1}),$$

for some $C_3, C_4, c_1 > 0$. For $T_{2n}$, note that

$$T_{2n} \leq C_5 \omega_0^{-(1+\lambda_0)} \frac{\exp(-2/\mu h^\lambda)}{h^{(2r+1)+2(1+\lambda_0)}} \int_{|\omega| > \epsilon} |K^{\beta}(\omega)| \exp \left( \frac{|\omega|^\lambda}{h^\lambda \mu} \right) d\omega,$$

for some $C_5 > 0$. By an analogous dominated convergence argument used in the proof of Lemma 8, we can show $T_{2n}$ converges to some finite constant. Combining these results, the conclusion follows. 

\textbf{APPENDIX C. Assumptions and proof for Theorem 3}

In this appendix we prove Theorem 3, the asymptotic distribution of $s_n$ in (18). Basic steps of our proof follow the recipe laid down by Bissantz, Dümbgen, Holzmann and Munk (2007). Importantly, we impose tail conditions on $f^{\beta}_t$ of the form $f^{\beta}_t(\omega)|\omega|^\beta \to C_\beta$ as $|\omega| \to \infty$. Based on this, we define

$$\mathcal{K}(u) = \frac{1}{2\pi C_\epsilon} \int_0^\infty e^{-iu \omega} K^{\beta}(\omega) d\omega + \frac{1}{2\pi C_\epsilon} \int_{-\infty}^0 e^{-iu \omega} |\omega|^\beta K^{\beta}(\omega) d\omega,$$

$$\mathcal{L}(u) = \frac{1}{2\pi C_\epsilon} \int_0^\infty \sin(\omega u) \omega^\beta - 1 K^{\beta}(\omega) d\omega + \frac{1}{2\pi C_\epsilon} \int_{-\infty}^0 \sin(\omega u) |\omega|^\beta \omega^\beta - 1 K^{\beta}(\omega) d\omega. \quad (44)$$

These are the pointwise limits of $h^{\beta} \mathcal{K}(u)$ and $h^{\beta} \mathcal{L}(u)$ as $h \to 0$ under some assumptions on $f^{\beta}_t$. In addition to Assumptions OS (i)-(iii), we impose the following conditions.

\textbf{Assumption G.}

(i): $f^{\beta}_t(\omega)|\omega|^\beta \to C_\beta$ as $|\omega| \to \infty$ for some $\beta > 1/2$.

(ii): $h^\beta \int |\mathcal{K}(u)| du < M$ for some $M > 0$ independent of $h$. $\int |u|^{3/2} \sqrt{\log \log |u|} |\mathcal{K}(u)| du < \infty$. For some $\delta > 0$, $\int |h^{\beta} \mathcal{K}(u) - \mathcal{K}(u)| du = O(h^{1/2+\delta})$.

(iii): $\lim_{u \to \pm \infty} |\mathcal{L}(u)| = 0$. For some $\delta_1 \in (0, 1)$, $\int |\mathcal{L}(u)|^{2-\delta_1} du < \infty$. For some $\delta > 0$, $\sup_u |h^{\beta} \mathcal{L}(u/h) - \mathcal{L}(u/h)| = O(h^{1/2+\delta})$.

(iv): $f_\lambda$ and its derivative $f_\lambda'$ are bounded and continuous on $\mathbb{R}$ such that $\lim_{x \to \pm \infty} |x f_\lambda'(x) \log(\log^+ |x|)| = 0$. Also, $\sup_x |f_\lambda'(x) f_\lambda(x)^{-1/2} \sqrt{|x| \log(\log^+ |x|)}| < \infty$. Furthermore it holds $\int |f_\lambda(x) f_\lambda(x)^{-1/2} \sqrt{|x| \log(\log^+ |x|)}| dx < \infty$.

These conditions are generalizations and simplifications of the ones in Bissantz, Dümbgen, Holzmann and Munk (2007). Assumption G (i) is stronger than the usual assumption $f^{\beta}_t(\omega)|\omega|^\beta < C_\beta$ as $|\omega| \to \infty$ but is required for explicit derivation of the limiting distribution.

Note that $\mathcal{L}(u) = \frac{1}{2\pi} \int_{-\infty}^\infty \frac{e^{-iu \omega} K^{\beta}(\omega)\chi_{\{\omega \geq \omega_0\}}}{h^{\beta} \omega^\beta} d\omega$. This integral exists due to the truncation.
Assumption G (ii) contains conditions for the deconvolution kernel $K$. The first condition ensures that $K$ is $L_1$-integrable. A sufficient condition for this is that $1/f_r^h(\omega)$ is a polynomial function in $\omega$. Indeed in this case it can be shown from the properties of the Fourier transform that $|K(u)| \sim |u|^{-q}$ as $|u| \to \infty$ under some conditions on $f_r^h$. For instance, the choice $r > 2$ for $K$ assures $|K(u)| \sim |u|^{-2}$ under the assumption

$$
\int \left| \frac{K^h(\omega)}{f_r^h(\omega/h)} \right|^2 d\omega = O(h^{-\beta}).
$$

A similar condition is given in, for example, Bissantz, Dümbgen, Holzmann and Munk (2007, eq. (13)). $K$ in (44) is the limit of $\bar{K}$ as $h \to \infty$ obtained by Assumption G (i). Recall that by Assumption OS (ii), $h^{\frac{1}{2}} \int ||K(u)| - \bar{K}(u)||d\omega = O(h^\delta)$. Additionally, it can be shown from the previous assumptions and properties of the Fourier transform of $\omega^\beta K^h(\omega)$ that $\int |h^\beta K(u) - K(u)|d\omega < \infty$. To obtain the rate $h^{1/2+\delta}$ for the latter, we need some additional conditions on the decay of $f_r^h$. Denote $R(\omega) = f_r^h(\omega)\omega^\beta - C_\beta$. Then a sufficient condition for the third condition in Assumption G (ii) is that $R(\omega) \sim \omega^{-1/2-\delta}$ as $|\omega| \to \infty$.

Assumption G (iii) contains conditions on the integrated kernel function $L$. On the first two conditions in Assumption G (iii), we can in fact show the stronger statement that for all the commonly used kernel functions, $L(u) \sim |u|^{-\beta+1}$ as $u \to \pm \infty$. Regarding the third condition in Assumption G (iii), note that we can expand

$$
h^\beta L \left( \frac{u}{h} \right) - L \left( \frac{u}{h} \right) = h^\beta \frac{\pi C_\beta}{2} \int_{\omega_1}^{1/h} \frac{\sin(\omega u)}{\omega} K^h(h\omega) R(\omega) \frac{d\omega}{\omega^\beta} - h^\beta \frac{\pi C_\beta}{2} \int_0^{\omega_1} \sin(\omega u) \omega^{\beta-1} K^h(h\omega) d\omega.
$$

Standard arguments show that this is of the order $h^{1/2+\delta}$ under the assumption $R(\omega) \sim \omega^{-1/2-\delta}$ as $|\omega| \to \infty$.

Assumption G (iv) provides conditions on the decay rates of the pdf $f_X$ and its derivative $f_X'$. Similar assumptions are adopted in the literature (e.g., Bickel and Rosenblatt, 1973).

Based on these conditions, we obtain Theorem 3 with

$$
B = \int L(a)^2 da, \quad b_n = (-2 \log h)^{1/2} + (-2 \log h)^{-1/2} \log \left( \frac{\int L'(a)^2 da}{4\pi B} \right), \quad (45)
$$

Furthermore, if we consider the simple hypothesis

$$
H_0 : F_{X^*}(t) = F_0(t) \quad \text{for } t \in T,
$$

for some $F_0$, a test statistic for $H_0$ is $t_n^0 = \sup_{t \in T} |f_X(t)^{-1/2} \{F_{X^*}(t) - F_0(t)\}|$. Consider the sequence of local alternatives

$$
H_{1n} : F_{X^*}(t) = F_0(t) + \gamma_n \eta(t) \quad \text{for } t \in T,
$$

where $\eta(t)$ is a continuous function and $\gamma_n = \sqrt{n}h^{\beta-1/2}(2 \log(1/h))^{1/2}$. By an analogous argument, we can obtain

$$
P \left\{ (-2 \log h)^{1/2}(B^{-1/2}t_n^0 - b_n) \leq c \right\} \to \exp(-s(\eta) \exp(-c)),
$$

for all $c \in \mathbb{R}$, where $s(\eta) = \int_0^1 \exp((Bf_{X^*}(a))^{-1/2}\eta(a)) + \exp(-(Bf_{X^*}(a))^{-1/2}\eta(a)) da$.
C.1. **Proof of Theorem 3.** We show that

\[
\sup_{t \in T} \left| \sqrt{nh^{2\beta - 1}f_X(t)^{-1}} \{ \tilde{F}_X^*(t) - F_X(t) \} - \mathcal{Y}_n(t) \right| = o_p((\log(h))^{-1/2}),
\]

where \( \mathcal{Y}_n = h^{-1/2} \int L \left( \frac{t - a}{h} \right) dW(a) \) is a Gaussian process. Once we obtain (46), the conclusion follows by applying the arguments of Bickel and Rosenblatt (1973, Theorem A1). The rate \( o_p((\log(h))^{-1/2}) \) is required because later we scale by \((\log(h))^{1/2}\) to obtain the limiting distribution as in Bickel and Rosenblatt (1973).

First, as in the proof of Lemma 2, the bias term in \( Q_n(t) \) is negligible and we can restrict attention to the mean zero process

\[
D_n(t) = Q_n(t) - E[Q_n(t)] = h^{\beta - 1/2} \int L \left( \frac{t - a}{h} \right) d\alpha_n(a),
\]

where \( \alpha_n(a) = \sqrt{n} \{ F_{X,n}^E(a) - F_X(a) \} \) is the empirical process, and \( F_{X,n}^E \) is the empirical distribution function by \( \{X_i\}_{i=1}^n \). We approximate \( D_n(t) \) by

\[
D_{n,1}(t) = h^{\beta - 1/2} \int L \left( \frac{t - a}{h} \right) dW(F_X(a)).
\]

Indeed the arguments in the proof of Lemma 2 allow us to show

\[
\sup_{t \in T} |D_n(t) - D_{n,1}(t)| = O_p((nh)^{-1/2} \log n)).
\]

Also, \( D_{n,1}(t) \) has the same finite dimensional distribution as

\[
D_{n,2}(t) = h^{\beta - 1/2} \int L \left( \frac{t - a}{h} \right) f_X(a)^{1/2} dW(a).
\]

Next, we approximate \( D_{n,2}(t) \) by

\[
D_{n,3}(t) = h^{-3/2} \int K \left( \frac{t - a}{h} \right) f_X(a)^{1/2} W(a) da.
\]

To this end, note that for any \( h > 0 \),

\[
\lim_{a \to \pm \infty} K \left( \frac{t - a}{h} \right) f_X(a)^{1/2} W(a) \leq \sup_a |K(u)| \lim_{a \to \pm \infty} |a f_X(a) \log(\log^+ |a|)|^{1/2} = 0,
\]

where the inequality follows from the law of the iterated logarithm for the Wiener process and the equality follows from the facts \( \sup_u |K(u)| = O(h^{-\beta - 1}) \) and Assumption G (iv). Thus, using stochastic integration by parts, we can write

\[
D_{n,2}(t) = h^{\beta - 1/2} \int \left\{ f_X(t - hu)^{1/2} \tilde{K}(u) + h f_X'(t - hu)f_X(t - hu)^{-1/2} \tilde{L}(u) \right\} W(t - hu) du.
\]

and obtain

\[
|D_{n,2}(t) - D_{n,3}(t)| \leq h^{-1/2} \int \{ h^{\beta} \tilde{K}(u) - K(u) \} f_X(t - hu)^{1/2} W(t - hu) du + h^{1/2} \int h^{\beta} \tilde{L}(u) f_X'(t - hu) f_X(t - hu)^{-1/2} W(t - hu) du = T_{n,4}(t) + T_{n,5}(t).
\]
Now by the law of the iterated logarithm and Assumption G (ii) and (iv), it follows $\sup_{t \in \mathcal{T}} |T_{n,4}(t)| = O_p(h^\delta)$. For the term $T_{n,5}(t)$,
\[
|T_{n,5}(t)| \leq h^{-1/2} \sup_u |h^\delta L(u/h) - L(u/h)| \int |f'_X(t-z)f_X(t-z)^{-1/2}W(t-z)|dz
\]
\[+ h^{1/2} \left| \int L(u)f'_X(t-hu)f_X(t-hu)^{-1/2}W(t-hu)du \right| = T_{n,51}(t) + T_{n,52}(t).
\]

Using Assumption G (iii)-(iv), an application of the law of the iterated logarithm proves $\sup_{t \in \mathcal{T}} T_{n,51}(t) = O(h^\delta)$. Next, for the term $T_{n,52}(t)$, Hölder’s inequality and the law of the iterated logarithm imply
\[
T_{n,52}(t) \leq h^{\delta_1/(1-2\delta_1)} \|L(u)\|_{2-\delta_1} \left| f'_X(u)f_X(u)^{-1/2} \sqrt{|u| \log(\log(1+|u|))} \right|^{2+\delta_1/(1-\delta_1)}.
\]

By this expression and Assumption G (iii)-(iv), we are able to show $\sup_{t \in \mathcal{T}} |T_{n,52}(t)| = o_p((-\log(h))^{-1/2})$.

Combining these results, the claim $\sup_{t \in \mathcal{T}} |D_{n,2}(t) - D_{n,3}(t)| = o_p((-\log(h))^{-1/2})$ follows.

Third, we approximate the process $f_X(t)^{-1/2}D_{n,3}(t)$ with the process
\[
D_{n,4}(t) = h^{-3/2} \int K \left( \frac{t-a}{h} \right) W(a)da.
\]

Note that
\[
f_X(t)^{-1/2}D_{n,3}(t) - D_{n,4}(t) = h^{-1/2} \int \left( f_X(t)^{-1/2}f_X(t-hu)^{1/2} - 1 \right) K(u)W(t-hu)du.
\]

By the law of the iterated logarithm and Assumption G (ii) and (iv), it follows
\[
\sup_{t \in \mathcal{T}} |f_X(t)^{-1/2}D_{n,3}(t) - D_{n,4}(t)| = O_p(h^{1/2}).
\]

Fourth, let
\[
D_{n,5}(t) = h^{-1/2} \int L \left( \frac{t-a}{h} \right) dW(a).
\]

By stochastic integration by parts formula and Assumption G (ii),
\[
D_{n,4}(t) - D_{n,5}(t) = \left\{ \lim_{a \to -\infty} L \left( \frac{t-a}{h} \right) W(a) \right\} - \left\{ \lim_{a \to -\infty} L \left( \frac{t-a}{h} \right) W(a) \right\} = 0,
\]
for each $h$, which implies that $D_{n,4}(t) = D_{n,5}(t)$ for all $t \in \mathcal{T}$. Since $D_{n,5}(t)$ has the same finite dimensional distributions as the process $Y_n$, the claim in (46) follows.
